

# TOCHNOG PROFESSIONAL User's manual

Dennis Roddeman

April 17, 2024

# Contents

<b>1</b>	<b>Basic information</b>	<b>52</b>
1.1	How to perform a calculation and how to get started . . . . .	52
1.2	Pre- and postprocessing . . . . .	52
1.3	Space discretization, time discretization . . . . .	53
1.4	Program capabilities . . . . .	53
1.5	Files used by Tochnog . . . . .	55
<b>2</b>	<b>Equations</b>	<b>56</b>
2.1	Convection and diffusion of heat . . . . .	56
2.1.1	Convection-diffusion equation . . . . .	56
2.1.2	Convection to environment . . . . .	56
2.1.3	Radiation to environment . . . . .	56
2.2	Material deformation and flow . . . . .	57
2.2.1	Memory . . . . .	58
	Total Lagrange . . . . .	58
	Updated Lagrange . . . . .	58
2.2.2	Elasticity . . . . .	59
	Isotropy . . . . .	59
	Transverse Isotropy . . . . .	60
	Nonlinear elasticity polynomials . . . . .	60
	Power law nonlinear elasticity . . . . .	60
	Borja Tamagnini nonlinear elasticity . . . . .	61
	Lade nonlinear elasticity . . . . .	61
2.2.3	Elasto-Plasticity . . . . .	61
	CamClay plasticity model . . . . .	62

Cap1 plasticity model . . . . .	64
Cap2 plasticity model . . . . .	65
Compression limiting plasticity model . . . . .	65
di Prisco plasticity model . . . . .	66
di Prisco plasticity model with varying density . . . . .	67
Drucker-Prager plasticity model . . . . .	67
Generalised Non Associate CamClay for Bonded Soils plasticity model	68
Gurson plasticity model . . . . .	68
Hardening-Soil plasticity model . . . . .	68
Mohr-Coulomb plasticity model . . . . .	70
Mohr-Coulomb hardening-softening plasticity model . . . . .	70
Tension limiting plasticity model . . . . .	70
Von-Mises plasticity model . . . . .	71
Isotropic Hardening and softening . . . . .	71
Kinematic Hardening . . . . .	71
Plastic heat generation . . . . .	72
2.2.4 Hypo-Plasticity . . . . .	72
Masin law . . . . .	72
Masin clay law . . . . .	74
Wolffersdorff law . . . . .	77
Wolffersdorff law - extended Niemunis version . . . . .	78
Wolffersdorff pressure dependent initial void ratio extension . . . . .	79
Niemunis visco law . . . . .	79
Cohesion extension . . . . .	81
Intergranular strains extension . . . . .	81
ISA-Intergranular strains extension . . . . .	82

2.2.5	Damage . . . . .	83
	Mazars . . . . .	83
2.2.6	Average stress (hydrostatic compressibility) . . . . .	84
	Compressibility contribution . . . . .	84
2.2.7	Undrained groundflow analysis . . . . .	84
	Local capacity . . . . .	84
2.2.8	Thermal stresses . . . . .	85
	Expansion . . . . .	85
2.2.9	Hyper elasticity . . . . .	85
	Besseling . . . . .	86
	Blatz-Ko . . . . .	86
	Mooney-Rivlin . . . . .	86
	Neo-Hookean . . . . .	86
	Reduced polynomial . . . . .	86
	Volumetric . . . . .	87
2.2.10	Viscoelasticity . . . . .	88
	Maxwell chains . . . . .	88
2.2.11	Viscoplasticity . . . . .	88
	Exponential model . . . . .	88
	Power model . . . . .	88
2.2.12	Viscosity . . . . .	89
	Viscous heat generation . . . . .	89
2.3	Contact analysis . . . . .	90
2.3.1	Penalty formulation . . . . .	90
2.3.2	Friction and frictional heat generation . . . . .	90
2.4	Ground water flow . . . . .	91

2.4.1	Storage equation for fully saturated analysis . . . . .	91
2.4.2	Non-saturated analysis . . . . .	93
2.4.3	Consolidation analysis . . . . .	94
2.5	Wave equation . . . . .	95
2.6	Probabilistic distributions . . . . .	96
2.6.1	Generation of random field . . . . .	96
2.6.2	Local averaging . . . . .	97
2.6.3	Monte Carlo simulations . . . . .	98
2.6.4	Input data records . . . . .	99
<b>3</b>	<b>Input file, general remarks</b>	<b>100</b>
<b>4</b>	<b>Input file, initialization part</b>	<b>101</b>
4.1	<b>echo switch</b> (first record of initialization part) . . . . .	101
4.2	<b>number_of_space_dimensions</b> <i>number_of_space_dimensions</i> (second record of initialization part) . . . . .	101
4.3	<b>derivatives</b> (third record of initialization part, if specified) . . . . .	102
4.4	<b>beam_rotation</b> . . . . .	102
4.5	<b>condif_temperature</b> . . . . .	102
4.6	<b>groundflow_pressure</b> . . . . .	102
4.7	<b>groundflow_pressure_gradient</b> . . . . .	102
4.8	<b>groundflow_saturation</b> . . . . .	102
4.9	<b>groundflow_velocity</b> . . . . .	102
4.10	<b>materi_damage</b> . . . . .	102
4.11	<b>materi_acceleration</b> . . . . .	103
4.12	<b>materi_displacement</b> . . . . .	103
4.13	<b>materi_displacement_relative</b> . . . . .	103
4.14	<b>materi_history_variable</b> <i>number_of_variables</i> . . . . .	103

4.15	<b>materi_maxwell_stress</b> <i>number_of_chains</i> . . . . .	103
4.16	<b>materi_plasti_camclay_history</b> . . . . .	103
4.17	<b>materi_plasti_cap1_history</b> . . . . .	104
4.18	<b>materi_plasti_diprisco_history</b> <i>number_of_history_variables</i> . . . . .	104
4.19	<b>materi_plasti_f</b> . . . . .	104
4.20	<b>materi_plasti_f_nonlocal</b> . . . . .	104
4.21	<b>materi_plasti_generalised_non_associate_cam_clay_for_bonded_soils_history</b>	104

## 1 Basic information

### 1.1 How to perform a calculation and how to get started

Create an input file, e.g. **problem.dat**. The default input file is **tochnog.dat**, which will be used if no other input file is specified. Thus the command **tochnog tochnog.dat** yields output on the screen while **tochnog tochnog.dat > tochnog.out** redirects the output to a file.

So to get started do, for example, the following:

- **cd test/other**
- **tochnog condif1.dat**

Use the **condif1.dat** test to get started.

- Copy **condif1.dat** to **tochnog.dat**.
- Use your favorite editor to open the file **tochnog.dat** and study it.
- Change **echo** to **-yes**.
- Remove the parentheses (...) surrounding the **control\_print** statement and save the file.
- Run by typing **tochnog** or **tochnog tochnog** or **tochnog tochnog.dat**.
- Study the output on the screen.
- Study the **tochnog.log** file.
- Study the **tochnog.dbs** file. It contains the database after the calculation, and is an input file itself!

Read at least once the start of the data part introduction section.

### 1.2 Pre- and postprocessing

You can use **GID** both for preprocessing (mesh generation) and post processing (plotting). **GID** is commercially available at the **www.gidhome.com** Internet page. A free demo version of is available for download.

Alternatively to **GID** you can use **Mecway** for preprocessing **input\_abaqus** and post processing **control\_print\_gmsh**. **Mecway** is commercially available at the **mecway.com**

Internet page. It is very affordable, and also has build in FE calculations (mostly for mechanical engineering). A free demo version of Mecway is available for download.

You can also use **GMSH** both for preprocessing and post processing. **GMSH** is freely available at [www.geuz.org/gmsh](http://www.geuz.org/gmsh).

Postprocessing files are written for the visualization program **PARAVIEW**. The **PARAVIEW** program is freely available at [www.paraview.org](http://www.paraview.org).

Furthermore, postprocessing files are written for the visualization program **TECPLOT**. These **TECPLOT** are less well maintained then the files for other postprocessing programs.

With **GNU PLOT** you can plot files resulting from **control\_print\_history** and **control\_print\_data\_versus\_data**. Also any other x-y plotting program can be used for such files.

### 1.3 Space discretization, time discretization

The computational domain is divided into finite elements. The elements connect at nodes. Either one-dimensional (1D), two-dimensional (2D), three-dimensional (3D) or axi-symmetrical (2D) domains can be used.

Only first order in time equations are solved. Time derivatives are approximated with Euler backward time discretization.

### 1.4 Program capabilities

- Input  
Format free input. Words and no 'magic numbers' in rigidly defined columns are used. Boundary conditions can be imposed onto geometrical entities, as well as onto elements and nodes.
- Output/plotting  
Output can be printed over user-specified geometrical objects (points, lines, quadrilaterals,...) as well as at nodes.  
The history of each variable, and for functions of variables, can be printed over user-specified geometrical objects as well as at nodes.  
Interface files for the GID pre- and post processor.
- Finite elements  
1D, 2D and 3D. Tochnog mostly uses isoparametric elements. There are also springs, trusses, beams and contact-springs however.  
Linear and quadratic simplex elements (triangles, tetrahedrons). Linear and quadratic prism elements. A full family of first to fourth order bar, quadrilateral and brick elements.

- Mesh generation/refining/etc.  
Macro regions are automatically divided into finite elements.  
Local h-refinement  
Global h-refinement (more elements).  
Global p-refinement (polynomial refinement).
- Differential equations (materials)  
Convection-diffusion equation:
  - Temperature calculations.
Fluids:
  - Stokes and Navier-Stokes.
Solids:
  - Elasticity (isotropy and transverse isotropy).
  - Elasto-Plasticity (Von-Mises, Mohr-Coulomb, Gurson, etc.; plasticity surfaces can be arbitrarily combined).
  - Hypo-Plasticity (Von-Wolffersdorff, Masin, cohesion, intergranular strains, pressure dependent initial void ratio).
  - Damage.
  - Thermal stresses.
  - Hypoelasticity.
  - Viscoelasticity.
  - Viscoplasticity.
  - Viscosity.
Ground water flow equation:
  - Storage equation. - saturated and non-saturated - multiple phreatic levels - piping and lifting safety - fully coupled consolidation analysis
Wave equation.
- Interaction analysis  
Automatic fluid-solid interaction.  
Temperature effects on fluids, solids.
- Contact analysis  
Contact with and without friction.  
Frictional heat generation.
- Frames of description  
Lagrangian and Eulerian
- Types of analysis  
Static, quasi-static and dynamic analysis.

- Parallelization  
Full shared memory parallelization node and element loops
- Special features  
Automatic time-stepping (large steps for good iteration behavior, small steps for bad iteration behavior).  
Automatic distribution of tendon trusses over finite elements (automatic embedment).  
Restart possibility.  
Convection wiggle stabilization (both for low and high order elements).

## 1.5 Files used by Tochnog

- Input file. For example **condif1.dat**. The input file consists of an initialization part (which dof's should be solved, etc.) and a data part (elements, nodes, etc.).
- Runtime input file. For example **condif1.run**. Use it to give Tochnog data records on the fly (while it is running).
- Plot files. For example **condif1\_flavia.msh** and **condif1\_flavia.res**.
- Database file. For example, after the calculation with input file **condif1.dat** the database file **condif1.dbs** will be written. It contains everything (nodes, elements, solutions fields, etc.). On error exit for example **condif1\_error.dbs** will be generated.
- Scratch file **tochnog\_tmp.txt**. Don't use this name yourself.
- Log file **tochnog.log**. Contains log messages of calculations.

## 2 Equations

### 2.1 Convection and diffusion of heat

#### 2.1.1 Convection-diffusion equation

$$\rho C(\dot{T} + \beta_i \frac{\partial T}{\partial x_i}) = k_i \frac{\partial^2 T}{\partial x_i^2} - aT + f$$

The primary dof is the **condif\_temperature**  $T$ . Further notation:  $\rho$  **group\_condif\_density**;  $C$  **group\_condif\_capacity**;  $x$  space coordinate;  $\beta_i$  **group\_condif\_flow** in  $i$ -direction;  $k_i$  **group\_condif\_conductivity** in  $i$ -direction;  $a$  **group\_condif\_absorption**;  $f$  **condif\_heat\_volume**. Typical applications are heat conduction and heat conduction in a flow.

#### 2.1.2 Convection to environment

$$q_c = \alpha_c(T - T_c)$$

Here  $q_c$  is the **condif\_convection\_edge\_normal** heat flux,  $\alpha_c$  is the convection coefficient and  $T_c$  is the environmental temperature for convection.

#### 2.1.3 Radiation to environment

$$q_r = \alpha_r(T^4 - T_r^4)$$

Here  $q_r$  is the **condif\_radiation\_edge\_normal** heat flux,  $\alpha_r$  is the radiation coefficient and  $T_r$  is the environmental temperature for radiation.

## 2.2 Material deformation and flow

$$\rho \dot{v}_i = \frac{\partial \sigma_{ij}}{\partial x_j} + (1 - \beta T) \rho g_i - d v_i + f_i$$

Notations:  $\rho$  **group\_materi\_density**;  $v_i$  **materi\_velocity** in  $i$ -direction;  $\sigma_{ij}$  **materi\_stress** matrix;  $x$  space coordinate;  $\beta$  **group\_materi\_expansion\_volume**;  $T$  (optional) **condif\_temperature**;  $g_i$  **force\_gravity**;  $d$  is the **group\_materi\_damping** coefficient (see also the dynamics section near the end of this manual);  $f_i$  **force\_volume**. The equation is given for space coordinates following the material velocities  $v_i$ .

TOCHNOG allows you to build your favorite material, by adding separate contributions to the stresses  $\sigma_{ij}$ . In this way you can build solids or fluids or things in between. The separate contributions will be listed below. First two typical examples are given.

Nearly incompressible Navier Stokes:

```
...
materi_velocity
materi_stress
end_initia
...
mesh -fixed_in_space -fixed_in_space
timestep_predict_velocity 0 -yes
...
group_type 0 -materi
group_materi_elasti_compressibility 0 1.0
group_materi_viscosity 0 1.2
...
```

Linear solid:

```
...
materi_velocity
materi_velocity_integrated
materi_stress
end_initia
...
group_type 0 -materi
group_materi_elasti_young 0 1.e10
group_materi_elasti_poisson 0 0.2
group_materi_memory 0 -updated_linear
```

### 2.2.1 Memory

#### The -**updated** Lagrange formulation

Deformations (i.e. the incremental deformation matrix  $F$ ) refers to the previous time point. TOCHNOG decomposes the incremental deformation tensor with a polar decomposition into  $F = RU$  with  $F$  the incremental deformation matrix,  $R$  the incremental rotation matrix and  $U$  the incremental stretch matrix. The incremental stretch matrix  $U$  is used to determine the incremental strain matrix  $0.5(U + U^T) - I$  with  $I$  the identity tensor. The stresses at a new timepoint are calculated as:

- calculate extra stresses due to incremental strain matrix
- add these extra stresses to the stresses of the previous time point
- rotate these new stresses by the matrix  $R$

#### The -**updated** **jaumann** Lagrange formulation

Deformations (i.e. the incremental deformation matrix  $F$ ) refers to the previous time point. The incremental stretch matrix  $U$  is used to determine the incremental strain matrix  $0.5(F + F^T) - I$  with  $I$  the identity tensor. The incremental rotation matrix  $R$  is  $0.5(F - F^T) + I$ . The stresses at a new timepoint are calculated as:

- calculate extra stresses due to incremental strain matrix
- add these extra stresses to the stresses of the previous time point
- rotate these new stresses by the matrix  $R$

#### The -**updated** **linear** Lagrange formulation

Deformations (i.e. the incremental deformation matrix  $F$ ) refers to the previous time point. Any rigid body rotation between the two time points are neglected, so TOCHNOG decomposes the incremental deformation tensor with a polar decomposition into  $F = U$  with  $F$  the incremental deformation matrix, and  $U$  the incremental stretch matrix. The linear engineering strains in the deformed configuration are used as incremental strain matrix  $0.5(F + F^T) - I$ . The stresses at a new timepoint are calculated as:

- calculate extra stresses due to incremental strain matrix
- add these extra stresses to the stresses of the previous time point

#### The -**total** Lagrange formulation

Deformations (i.e. the total deformation matrix  $F$ ) refers to the time 0. TOCHNOG decomposes the total deformation tensor with a polar decomposition into  $F = RU$  with  $F$

the total deformation matrix,  $R$  the total rotation matrix and  $U$  the total stretch matrix. The total stretch matrix  $U$  is used to determine the total strain matrix  $0.5(U + U^T) - I$  with  $I$  the identity tensor. The stresses at a new timepoint are calculated as:

- back-rotate the old stresses at the previous time point to time 0 with the old rotation matrix
- calculate extra stresses due to incremental strain matrix
- add these extra stresses to the back-rotated old stresses of the previous time point
- rotate the added stresses with the new rotation matrix  $R$  to the new configuration

#### The -total linear Lagrange formulation

Deformations (i.e. the total deformation matrix  $F$ ) refers to the time 0. TOCHNOG neglects any rigid body rotations and uses linear engineering strains  $0.5(F + F^T) - I$ . The difference in these linear engineering strains between two time points are the incremental strains.

The stresses at a new timepoint are calculated as:

- calculate extra stresses due to incremental strain matrix
- add these extra stresses to the stresses of the previous time point

See also `group_materi_memory`.

### 2.2.2 Elasticity

The elastic stress rate is

$$C_{ijkl}\dot{\epsilon}_{kl}^{\text{elas}}$$

where  $C_{ijkl}$  is the elastic modulus tensor (which is a doubly symmetric tensor:  $C_{ijkl} = C_{jikl}$ ,  $C_{ijkl} = C_{ijlk}$  and  $C_{ijkl} = C_{jilk}$ ), and  $\dot{\epsilon}_{kl}^{\text{elas}}$  is the elastic strain rate. See the plasticity section for a definition of the elastic strain rate.

For an isotropic material

$$\begin{aligned} C_{0000} &= C_{1111} = C_{2222} = \frac{E(1-\nu)}{(1+\nu)(1-2\nu)} \\ C_{0011} &= C_{0022} = C_{1122} = \frac{E\nu}{(1+\nu)(1-2\nu)} \\ C_{0101} &= C_{0202} = C_{1212} = \frac{E}{1+\nu} \end{aligned}$$

with  $E$  **group\_materi\_elasti\_young** modulus and  $\nu$  **group\_materi\_elasti\_poisson** ratio (the remaining non-zero moduli follow from the double symmetry conditions).

For a transverse isotropic material the material has one unique direction (think of an material with fibers in one direction). Here we take '2' as the unique direction; '1' and '3' are the transverse directions. The material is fully defined by  $E_1$ ,  $E_2$ ,  $\nu_1$ ,  $\nu_2$ , and  $G_2$ . This set of parameters leads directly to a set of elasticity coefficients  $C_{ijkl}$ . The parameters can be given in **group\_materi\_elasti\_transverse\_isotropy**,

The nonlinear elasticity polynomials is a strain dependent model. In this model, the 'young's stiffness' modulus is made dependent of the size of the strains via a series of polynomials

$$E = E_0 + E_1\epsilon^1 + E_2\epsilon^2 + \dots \quad (1)$$

where

$$\epsilon = \sqrt{(\epsilon_{ij}\epsilon_{ij})} \quad (2)$$

with  $\epsilon_{ij}$  the components of the strain matrix. The parameters  $E_0$  etc. need to be specified in the **group\_materi\_elasti\_young\_polynomial** record.

If the pressure state in a point is positive, we apply  $E = E_0$ .

The power law nonlinear elasticity is a stress dependent model which typically is used to model the elastic behavior of granular materials. It can be combined with plastic models, for example with the di Prisco plasticity model for soils, and with a poisson ratio.

In this model, the 'young's stiffness' modulus is made a function of the average stress state:

$$E = E_0 + E_1(p/p_1)^\alpha \quad (3)$$

with conditions however:

$$E \geq E_2 \quad (4)$$

$$E \leq E_3 \quad (5)$$

where  $p$  is the pressure. The parameters  $E_0$ ,  $E_1$ ,  $E_2$ ,  $E_3$ ,  $p_1$ , and  $\alpha$  need to be specified in the **group\_materi\_elasti\_young\_power** record.

In the **group\_materi\_elasti\_poisson\_power** model, the poisson ratio is made a function of the average stress state:

$$\nu = \nu_0 + \nu_1(p/p_1)^\alpha \quad (6)$$

with condition however:

$$\nu \leq \nu_2 \quad (7)$$

where  $p$  is the pressure. The parameters  $\nu_0$ ,  $\nu_1$ ,  $\nu_2$ ,  $p_1$ , and  $\alpha$  need to be specified in the **group\_materi\_elasti\_poisson\_power** record.

The stiffness matrix  $C_{ijkl}$  for the Borja Tamagnini nonlinear elasticity model is specified in

The model contains  $G_0$ ,  $\alpha$ ,  $\hat{k}$  and  $p_r$  as user specified constants which need to be specified in the **group\_materi\_elasti\_borja\_tamagnini** record.

The Lade nonlinear elasticity is a stress dependent model which typically is used to model the elastic behavior of granular materials. It can be combined with plastic models, for example with the di Prisco plasticity model for soils.

The stress rates are linked to the strain rates by the equation:

$$\dot{\epsilon}_{ij} = \frac{\partial W^2}{\partial \sigma_{ij} \partial \sigma_{hk}} \dot{\sigma}_{hk} \quad (8)$$

where the function  $W$  is

$$W = \frac{X^{1-\lambda}}{2B(1-\lambda)}$$

where

$$X = p^2 + R^* \text{abs}(s_{ij}s_{ij})$$

with pressure  $p = (\sigma_{11} + \sigma_{22} + \sigma_{33})/3$  and deviatoric stresses  $s_{ij} = \sigma_{ij} - p\delta_{ij}$ .

The model contains three user specified constants  $B$ ,  $R$ ,  $\lambda$  which need to be specified in the **group\_materi\_elasti\_lade** record.  $B$  and  $\lambda$  are defined by means of an isotropic unloading test, and  $R$  by means of an unloading-standard-triaxial-compression test. For example for a loose sand  $B = 1028$ ,  $R = 0.25$ ,  $\lambda = 0.28$ . See [10] for the details.

The model cannot be used in combination with a poisson ratio.

### 2.2.3 Elasto-Plasticity

#### Plastic strain

In plastic analysis, the **materi\_strain\_elasti** rate follows by subtracting from the **materi\_strain\_total** rate the **materi\_strain\_plasti** rate

$$\dot{\epsilon}_{ij}^{\text{elas}} = \dot{\epsilon}_{ij} - \dot{\epsilon}_{ij}^{\text{plas}}$$

where the **materi\_strain\_total** rate is

$$\epsilon_{ij} = 0.5 \left( \frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i} \right)$$

The **materi\_strain\_plasti** rate follows from the condition that the stress cannot exceed the yield surface. This condition is specified by a yield function  $f^{\text{yield}}(\sigma_{ij}) = 0$ . The direction of the plastic strain rate is specified by the stress gradient of a flow function  $\frac{\partial f^{\text{flow}}}{\partial \sigma_{ij}}$ . If the yield function and flow function are chosen to be the same, the plasticity is called associative, otherwise it is non-associative.

Von-Mises is typically used for metal plasticity. Mohr-Coulomb and Drucker-Prager are typically used for soils and other frictional materials. *The plasticity models can freely be combined; the combination of the plasticity surfaces defines the total plasticity surface.*

Typically, if you use Mohr-Coulomb or Drucker-Prager to model shear failure for soils, you should use the tension limiting model to limit tension stresses, preferably **group\_materi\_plasti\_tension\_direct**

First some stress quantities which are used in most of the plasticity models are listed.

Equivalent Von-Mises stress:

$$\bar{\sigma} = \sqrt{\frac{s_{ij}s_{ij}}{2}}$$

Mean stress:

$$\sigma_m = \frac{\sigma_{11} + \sigma_{22} + \sigma_{33}}{3}$$

Deviatoric stress:

$$s_{ij} = \sigma_{ij} - \sigma_m \delta_{ij}$$

### CamClay plasticity model

Here we provide the equations of the Cam Clay model (Roscoe and Burland, 1968, summarized e.g. by Wood, 1990, see [20]). All stresses are effective (geotechnical) stresses, i.e. compression is positive! Definitions of variables:

$$p = (\sigma_1 + \sigma_2 + \sigma_3)/3$$

$$q = \left\{ \frac{1}{2} [(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2] \right\}^{1/2}$$

in the principal stress axes. The CamClay yield rule, which is also the flow rule, reads:

$$f = g = q^2 - M^2[p(p_0 - p)] = 0$$

$M$  is a soil constant and  $p_0$  is a history (hidden) variable which corresponds to the preconsolidation mean pressure. The hardening function, evolution, of  $p_0$  reads:

$$dp_0 = \frac{p_0(1+e)d\varepsilon_v^p}{\lambda - \kappa}$$

in which

$$d\varepsilon_v^p = d\varepsilon_{11}^p + d\varepsilon_{22}^p + d\varepsilon_{33}^p$$

and  $\lambda$  and  $\kappa$  are user specified soil constants. Further  $e$  is the void ratio with the evolution equation:

$$de = -d\varepsilon_v(1+e)$$

in which

$$d\varepsilon_v = d\varepsilon_{11} + d\varepsilon_{22} + d\varepsilon_{33}$$

Notice that this is a geometrical linear approximation for void ratio changes. The poisson ratio  $\nu$  reads:

$$\nu = \frac{3K - 2G}{2G + 6K}$$

in which the elastic bulk modulus  $K$  is given by:

$$K = (1+e)p/\kappa$$

and the Young's modulus  $E$ :

$$E = 2 * G * (1 + \nu)$$

in which  $G$  is a user specified soil constant, By using this  $\nu$  and  $E$  the classical isotropic stress-strain law is used to calculate the stresses.

The soil constants  $M$ ,  $\kappa$ ,  $\lambda$  need to be specified in **group\_materi\_plasti\_camclay**. The soil constant  $G$ , need to be specified in **group\_materi\_elasti\_camclay\_g**. For an alternative see **group\_materi\_elasti\_camclay\_poisson**. The history variables  $e$ ,  $p_0$  need to be initialized by **materi\_plasti\_camclay\_history** record (and given initial values in **node\_dof** records).

Remark 1: An additional parameter  $N$  can be often found in textbooks on the Cam Clay model. We don't include it since it is linked to other model parameters via:

$$1 + e = N - \lambda \ln p_0 + \kappa \ln(p_0/p)$$

Remark 2: If you apply a geometrical linear analysis, see section 8.4, then also the calculation of de void ratio development is linearized, and so will contain some error as compared to the exact void ratio change. Hence for very large deformations, say above 10 percent or so, don't use such geometrical linear analysis.

Remark 3: This camclay law is very sensitive for near-zero stresses. It is best to only use it in combination with application of initial gravity stresses by means of **control\_reset\_dof**.

#### Cap1 plasticity model

This **group\_materi\_plasti\_cap1** model is the first cap model that accounts for permanent plastic deformations under high pressures for granular materials. It is intended to be used in combination with shear plasticity models like Drucker-Prager, Mohr-Coulomb, etc.

First the average stress  $p$  and the equivalent shear stress  $q$  are introduced:

$$p = -(\sigma_{11} + \sigma_{22} + \sigma_{33})/3$$

$$q = \left\{ \frac{1}{2} [(\sigma_{11} - \sigma_{22})^2 + (\sigma_{22} - \sigma_{33})^2 + (\sigma_{33} - \sigma_{11})^2] + 3(\sigma_{12}^2 + \sigma_{23}^2 + \sigma_{31}^2) \right\}^{1/2}$$

These are used to define the cap plastic yield function:

$$f = \frac{q^2}{M^2} + p^*(p^* - p_c^*)$$

where

$$p^* = p + c \cot \phi \quad p_c^* = p_c + c \cot \phi$$

The parameter  $p_c$  is a history variable of this model. The parameter  $\phi$  is the coulomb friction angle in radians, and  $c$  is the cohesion. The parameter  $M$  denotes the tangent of the Critical State Line in the model, Typically you can use:

$$M = \frac{6 \sin \phi}{3 - \sin \phi}$$

The history parameter  $p_c$  is assumed to harden with the cap plastic volume strain rate according to the rate form:

$$\dot{\epsilon}_{cv}^p = \frac{\lambda^*/\kappa^* - 1}{K^{ref}} \left( \frac{p^{ref}}{p_c^*} \right)^m \dot{p}_c$$

Here  $\kappa^*$  is the swelling index (e.g. 0.03),  $\lambda^*$  is the compression index (e.g. 0.15),  $K^{ref}$  is the bulk modulus at stress  $p^{ref}$  (typically  $100kPa$ ), which typically can be taken as:  $K^{ref} = \frac{E^{ref}}{3(1-2\nu)}$ , and finally  $m$  is an exponent (e.g. 0.6).

Initialize **materi\_plasti\_cap1\_history** in the initialization part. The state variable  $p_c$  for this hardening soil model enters the **node\_dof** records. You need to give an initial value for it in the **node\_dof** records. See also [2].

### Cap2 plasticity model

This is the second cap model that accounts for permanent plastic deformations under high pressures for granular materials. It is intended to be used in combination with shear plasticity models like Drucker-Prager, Mohr-Coulomb, etc.

First a deviatoric stress measure  $t$  and hydrostatic stress measure  $p$  are defined

$$t = \sqrt{3}\bar{\sigma}$$

$$p = -\sigma_m$$

See above for  $\bar{\sigma}$  and  $\sigma_m$ . The yield rule for the **group\_materi\_plasti\_cap2** model reads:

$$f = \sqrt{(p - p_a)^2 + \left[ \frac{Rt}{(1 + \alpha - \frac{\alpha}{\cos\phi})} \right]^2} - R(c + p_a \tan\phi)$$

Here  $c$  is the cohesion and  $\phi$  is the friction angle which should be taken equal to the values in the shear flow rule which you use. The parameter  $p_a$  follows from

$$p_a = \frac{p_b - Rc}{1 + R \tan\phi}$$

where the hydrostatic compression yield stress  $p_b$  is to be defined with an table of volumetric plastic strains  $\epsilon_v^p$  versus  $p_b$  with  $\epsilon_v^p = \epsilon_{11}^p + \epsilon_{22}^p + \epsilon_{33}^p$ . As always, positive strain denote extension whereas negative strains denote compression.

Associative flow is used, so the flow rule is taken equal to the yield rule.

Summarizing the **group\_materi\_plasti\_cap2** model needs as input the cohesion  $c$ , the friction angle  $\phi$ , the parameter  $\alpha$  (typically  $1 \cdot 10^{-2}$  up to  $5 \cdot 10^{-2}$ ), and a table  $\epsilon_v^p$  versus  $p_b$ .

### Compression limiting plasticity model

This **group\_materi\_plasti\_compression** model uses a special definition for the equivalent stress

$$\bar{\sigma} = \sqrt{\sigma_{min}^2}$$

where  $\sigma_{min}$  is the largest compressive principal stress. The model now reads

$$\bar{\sigma} - \sigma_y = 0$$

This plasticity surface limits the allowed compressive stresses.

#### di Prisco plasticity model

The di Prisco model is an non-associative plastic model for soils, which can be typically combined with the 'Lade elastic model'. This di Prisco model is a rather advanced soil model, which is explained in more detail in [3] and [9]. The yield rule reads:

$$f = 3\beta_f(\gamma - 3) \ln\left(\frac{r}{r_c}\right) - \gamma J_{3\eta^*} + \frac{9}{4}(\gamma - 1)J_{2\eta^*}$$

and the flow rule yields:

$$g = 9(\gamma - 3) \ln\left(\frac{r}{r_g}\right) - \gamma J_{3\eta^*} + \frac{9}{4}(\gamma - 1)J_{2\eta^*}$$

This is an anisotropic model in which the first and second invariant of the stress rate  $\eta^*$  are defined relative to the rotation axes  $\chi$ .

$$\begin{aligned} r &= \sigma_{ij}\chi_{ij} \\ J_{3\eta^*} &= \eta_{ij}^*\eta_{jk}^*\eta_{ki}^* \\ J_{2\eta^*} &= \eta_{ij}^*\eta_{ij}^* \\ \eta_{hk}^* &= \sqrt{3}\frac{s_{hk}^*}{r} \end{aligned}$$

where  $s^*$  follows from

$$s_{hk}^* = \sigma_{hk}^* - r\chi_{hk}$$

Further  $r_g = 1$ .

The history variables are  $\chi_{ij}$  (rotation axes, 9 values),  $\beta$  (yield surface form factor), and  $r_c$  (preconsolidation mean pressure). The evolution laws for these history variables can be found in the papers listed above. The history variables  $\chi_{ij}$  (9 values),  $\beta$ ,  $r_c$  need to be initialized by the **group\_plasti\_diprisco\_history 11** record (and should be given initial values in **node\_dof** records). In a normally consolidated sand with isotropic initial conditions  $\chi_{ij} = \frac{\delta_{ij}}{\sqrt{3}}$ ,  $\beta = 0.0001$  and  $r_c$  equals  $\sqrt{3}$  times the means pressure.

The total model, yield rule and flow rule and evolution laws for history variables, contains a set of soil specific constants. In **group\_materi\_plasti\_diprisco** you need to specify these constants. These constants are explained in more detail in the papers mentioned above, but here we give a short explanation. The constants  $\hat{\theta}_c$ ,  $\hat{\theta}_e$ ,  $\xi_c$  and  $\xi_e$  are linked to the dilatancy and the stress state during failure (standard triaxial compression and extension test in drained conditions). The constants  $\gamma$ ,  $c_p$ ,  $\beta_f$  and  $\beta_f^0$  are defined by means of the experimental curves ( $q$ - $\epsilon_{axial}$ ,  $\epsilon_{vol}$ - $\epsilon_{axial}$ ) obtained by performing a standard compression test in drained conditions. Moreover,  $\beta_f$ ,  $\beta_f^0$  and  $t_p$  can also be determined by means of the effective-stress path obtained by performing a standard triaxial compression test in undrained conditions.

Finally  $b_p$  can be determined from an isotropic compression test. For a loose sand  $\hat{\theta}_c = 0.253$ ,  $\hat{\theta}_e = 0.0398$ ,  $\xi_c = -0.2585$ ,  $\xi_e = -0.0394$ ,  $\gamma = 3.7$ ,  $c_p = 18.$ ,  $\beta_f = 0.5$ ,  $\beta_f^0 = 1.1$ ,  $t_p = 10.$ , and  $b_p = 0.0049$ .

#### di Prisco plasticity model with varying density

This essentially is the same as the normal di Prisco model, but instead of one set of parameters you need to specify two sets of parameters, one of loose soil and one for dense soil. The actual applied parameters will then be interpolated from the loose parameters and dense parameters depending on the actual density of the soil. The parameters need to be specified in **group\_materi\_plasti\_diprisco\_density**.

The history variables are those of **group\_materi\_plasti\_diprisco** and finally extra the relative density (for example 20 or 40). So there are 12 history variables in total.

#### Drucker-Prager plasticity model

The **group\_materi\_plasti\_druck\_prag** model reads

$$\begin{aligned} 3\alpha\sigma_m + \bar{\sigma} - K &= 0 \\ \alpha &= \frac{2\sin(\phi)}{\sqrt{3}(3 - \sin(\phi))} \\ K &= \frac{6c\cos(\phi)}{\sqrt{3}(3 - \sin(\phi))} \end{aligned}$$

Here  $c$  is the cohesion, which needs to be specified both for the yield function and the flow rule; by choosing different values non-associative plasticity is obtained.

You should also include tension cut-off, preferably with **group\_materi\_plasti\_tension\_direct**.

#### Generalised Non Associate CamClay for Bonded Soils plasticity model

It is a modification of the 'Milan' model of Prof. Roberto Nova.

#### Gurson plasticity model

The **group\_materi\_plasti\_gurson** model reads

$$\frac{3\bar{\sigma}^2}{\sigma_y^2} + 2q_1 f^* \cosh(q_2 \frac{3\sigma_m}{2\sigma_y}) - (1 + (q_3 f^*)^2) = 0$$

Here  $f^*$  is the volume fraction of voids. The rate equation

$$\dot{f}^* = (1 - f^*) f^* \epsilon_{kk}^{\text{plas}}$$

defines the evolution of  $f^*$  if the start value for  $f^*$  is specified. Furthermore,  $q_1$ ,  $q_2$  and  $q_3$  are model parameters.

#### Hardening-Soil model

In this section, the principal stresses are ordered such that

$$\sigma_3 > \sigma_2 > \sigma_1$$

so that  $\sigma_1$  is the largest compressive stress. Likewise for the principal plastic strains:

$$\epsilon_3^p > \epsilon_2^p > \epsilon_1^p$$

First the elasticity parameters are defined. The elasticity parameters for the first loading are:

$$\text{Young's modulus} = E_{50} = E_{50}^{\text{ref}} \left( \frac{\sigma_3 + c \cot \phi}{\sigma_{50}^{\text{ref}} + c \cot \phi} \right)^m \quad \text{and Poisson's ratio} = \nu_{50}$$

The elasticity parameters for the elastic unloading and reloading are:

$$\text{Young's modulus} = E_{ur} = E_{ur}^{\text{ref}} \left( \frac{\sigma_3 + c \cot \phi}{\sigma_{ur}^{\text{ref}} + c \cot \phi} \right)^m \quad \text{and Poisson's ratio} = \nu_{ur}$$

The yield function reads:

$$f = \frac{1}{E_{50}} \frac{q}{1 - q/q_a} - \frac{2q}{E_{ur}} - \gamma^p$$

where  $q$  is the equivalent shear stress and  $\gamma^p$  is the equivalent plastic shear strain.

The equivalent asymptotic shear stress reads

$$q_a = \frac{q_f}{R_f}$$

in which  $q_f$  is the shear failure stress, and  $R_f$  is the failure ratio.

Specify all elasticity parameters in **group\_materi\_elasti\_hardsoil**. Typically you have:

- $E_{50}^{ref}$  from experiment at stress  $\sigma_{50}^{ref}$
- $\nu_{ur}$  from experiment or the typical undrained value 0.495 or the typical drained value 0.3
- $m$  from experiment or the typical value 0.5
- $E_{ur}^{ref}$  from experiment at stress  $\sigma_{ur}^{ref}$ , or the typical value  $3E_{50}^{ref}$
- $\nu_{ur}$  from experiment or the typical undrained value 0.495 or the typical drained value 0.2

Specify all plasticity parameters in **group\_materi\_plasti\_hardsoil**.

- $\phi$  from experiment (maximum friction angle)
- $c$  from experiment (cohesion)
- $\psi$  from experiment (maximum dilatancy angle)
- $R_f$  from experiment or the typical value 0.9 (failure ratio)

Initialize **materi\_strain\_plasti\_hardsoil** in the initialization part. This causes that the **node\_dof** records will be filled with the shear plastic strains. Also initialize **materi\_plasti\_hardsoil\_history**.

You can add an initial contribution to the  $\gamma^p$  by setting **control\_materi\_plasti\_hardsoil\_gammap\_initial** to **-yes**. This tells tochnog to create an extra contribution to  $\gamma^p$  exactly such that the yield function is zero-valued. This is convenient to start the calculation with hardsoil with deviatoric stresses which would have been outside the yield surface without this extra contribution. The extra addition to  $\gamma^p$  is saved in the record **element\_intpnt\_materi\_plasti\_hardsoil\_gammap\_in** for each integration point of elements. The creation of this extra initial contribution is done in the first timestep of the timesteps of the corresponding **control\_timestep** record with the same index.

See also [18] for some details. Especially notice that the model is more suited for monotonic loading than for load cycling (since it violates thermodynamics and tends to generate energy).

#### Mohr-Coulomb plasticity model

The **group\_materi\_plasti\_mohr\_coul** model reads

$$0.5(\sigma_1 - \sigma_3) + 0.5(\sigma_1 + \sigma_3) \sin(\phi) - c \cos(\phi) = 0$$

Here  $c$  is the cohesion,  $\sigma_1$  is the largest principal stress and  $\sigma_3$  is the smallest principal stress. The angle  $\phi$  needs to be specified for both the yield condition and the flow rule; by choosing different values, non-associative plasticity is obtained.

As an alternative consider using **group\_materi\_plasti\_mohr\_coul\_direct**, which is more stable and fast.

You should also include tension cut-off, preferably with **group\_materi\_plasti\_tension\_direct**.

#### Mohr-Coulomb hardening-softening plasticity model

The **group\_materi\_plasti\_mohr\_coul\_hardening\_softening** model is the same as the standard Mohr-Coulomb model. Now, however, the parameters  $c$  and  $\phi$  (both for the yield rule and for the flow rule) are softened on the effective plastic strain  $\kappa^{shear}$ .

For example, for the cohesion a linear variation is taken between the initial value  $c_0$  at  $\kappa^{shear} = 0$ , up to  $c_1$  at a specified critical value of  $\kappa^{shear}$ , and constant  $c_1$  for larger values of  $\kappa^{shear}$ . The same is done for  $\phi$  for the yield rule and for the flow rule.

You should also include tension cut-off, preferably with **group\_materi\_plasti\_tension\_direct**.

#### Tension limiting plasticity model

This **group\_materi\_plasti\_tension** model uses a special definition for the equivalent stress

$$\bar{\sigma} = \sqrt{\sigma_{max}^2}$$

where  $\sigma_{max}$  is the largest principal tension stress.

$$\bar{\sigma} - \sigma_y = 0$$

This plasticity surface limits the allowable tension stresses.

A simple model for concrete can be obtained as follows. Use **group\_materi\_plasti\_tension** to limit the tension strength  $ft$ . Use **group\_materi\_plasti\_vonmises** to limit the compressive strength  $fc$ . The tension strength could be softened to zero over an effective plastic strain  $\kappa$  of, say, 1 percent. The compressive strength could be softened to zero over an effective plastic strain  $\kappa$  of, say, 10 percent.

#### Von-Mises plasticity model

The **group\_materi\_plasti\_vonmises** model reads

$$\sqrt{3} \bar{\sigma} - \sigma_y = 0$$

where without hardening the yield value is fixed  $\sigma_y = \sigma_{y0}$ .

If however the **group\_materi\_plasti\_vonmises\_nadai** hardening law for Von-Mises plasticity is specified then

$$\sigma_y = \sigma_{y0} + C(\kappa_0 + \kappa)^n$$

where  $C$ ,  $\kappa_0$  and  $n$  are parameters for the hardening law, and  $\kappa$  is the isotropic hardening parameter (see later). The parameter  $\sigma_{y0}$  is specified by **group\_materi\_plasti\_vonmises**.

#### Isotropic Hardening and softening

The size of the total plastic strains rate is measured by the **materi\_plasti\_kappa** parameter

$$\dot{\kappa} = \sqrt{0.5 \dot{\epsilon}_{ij}^{\text{plas}} \dot{\epsilon}_{ij}^{\text{plas}}}$$

The size of the shear plastic strains rate is measured by the **materi\_plasti\_kappa\_shear** parameter

$$\dot{\kappa}^{\text{shear}} = \sqrt{0.5 \dot{\epsilon}_{ij}^{\text{shear,plas}} \dot{\epsilon}_{ij}^{\text{shear,plas}}}$$

where the plastic shear strains are defined by

$$\dot{\epsilon}_{ij}^{\text{shear,plas}} = \dot{\epsilon}_{ij}^{\text{plas}} - \delta_{ij}(\dot{\epsilon}_{11}^{\text{plas}} + \dot{\epsilon}_{22}^{\text{plas}} + \dot{\epsilon}_{33}^{\text{plas}})/3$$

These parameters  $\kappa$  and  $\kappa^{\text{shear}}$  can be used for isotropic hardening. Use the **dependency\_diagram** for this.

#### Kinematic Hardening

The **materi\_plasti\_rho** matrix  $\rho_{ij}$ , governs the kinematic hardening in the plasticity models. It is used in the yield rule and flow rule to get a new origin by using the argument  $\sigma_{ij} - \rho_{ij}$ .

$$\begin{aligned} f^{\text{yield}} &= f^{\text{yield}}(\sigma_{ij} - \rho_{ij}) \\ f^{\text{flow}} &= f^{\text{flow}}(\sigma_{ij} - \rho_{ij}) \end{aligned}$$

where the rate of the matrix  $\rho_{ij}$  is taken to be

$$\dot{\rho}_{ij} = a \epsilon_{ij}^{\text{plas}}$$

where  $a$  is a user specified factor (see **group\_materi\_plasti\_kinematic\_hardening**).

#### Plastic heat generation

The plastic energy loss can be partially turned into heat rate per unit volume  $q$ :

$$q = \eta \sigma_{ij} \epsilon_{ij}^{\text{plas}}$$

where  $\eta$  is a user specified parameter (between 0 and 1) specifying which part of the plastic energy loss is turned into heat (see **group\_materi\_plasti\_heat\_generation**).

### 2.2.4 Hypo-Plasticity

In hypoplasticity a direct relation is used between strain rates and effective stress rates. Rigid body rotations (objectivity) are treated elsewhere (see the section on memory). The effective stress tensor  $\sigma_{ij}$  follows from the total stress tensor  $\sigma_{ij}$  minus any pore pressures (see groundflow). The Masin law is tuned to clays. The Wolffersdorff law is tuned to sands but can also be used for clays. The Niemunis visco law describes time dependent soil behaviour. If you need a cyclic law, you should use the Wolffersdorff law with intergranular strains and especially specify the correct theta. For many cycles the isa-intergranular strain formulation can be used.

#### Masin law

The law proposed by MASIN [11] and [12] is used. This law is formulated in kPa; you need to make the remainder of the input file consistent with that.

The constitutive equation in rate form reads:

$$\dot{\mathbf{T}} = \mathcal{L} : \mathbf{D} + f_a \mathbf{N} \|\mathbf{D}\| \quad (9)$$

where  $\mathbf{D}$  is the Euler's stretching tensor,  $\mathbf{T}$  is the Cauchy stress tensor and

$$\mathcal{L} = 3f_s \left( c_1 \mathcal{I} + c_2 a^2 \hat{\mathbf{T}} \otimes \hat{\mathbf{T}} \right) \quad \mathbf{N} = \mathcal{L} : \left( -Y \frac{\mathbf{m}}{\|\mathbf{m}\|} \right) \quad \hat{\mathbf{T}} = \frac{\mathbf{T}}{\text{tr } \mathbf{T}} \quad (10)$$

$\mathbf{1}$  is the second-order identity tensor and  $\mathcal{I}$  is the fourth-order identity tensor, with components:

$$(\mathcal{I})_{ijkl} = \frac{1}{2} (1_{ik}1_{jl} + 1_{il}1_{jk}) \quad (11)$$

The functions  $f_s(\text{tr } \mathbf{T})$  (*barotropy* factor) and  $f_d(\text{tr } \mathbf{T}, e)$  (*pyknnotropy* factor) are given by:

$$f_s = -S_i \frac{\text{tr } \mathbf{T}}{\lambda^*} \left(3 + a^2 - 2^\alpha a \sqrt{3}\right)^{-1} f_d = \left[ -\frac{2\text{tr } \mathbf{T}}{3sp_r} \exp\left(\frac{\ln(1+e) - N}{\lambda^*}\right) \right]^\alpha \quad (12)$$

where  $p_r$  is the reference stress for the parameter  $N$ , typically taken as 1 kPa, and the factor  $S_i$  is a function of sensitivity  $s$ :

$$S_i = \frac{s - k(s - s_f)}{s} \quad (13)$$

The scalar function  $Y$  and the second-order tensor  $\mathbf{m}$  are given, respectively, by:

$$Y = \left( \frac{\sqrt{3}a}{3 + a^2} - 1 \right) \frac{(I_1 I_2 + 9I_3)(1 - \sin^2 \varphi_c)}{8I_3 \sin^2 \varphi_c} + \frac{\sqrt{3}a}{3 + a^2} \quad (14)$$

in which:

$$I_1 = \text{tr } \mathbf{T} \quad I_2 = \frac{1}{2} \left[ \mathbf{T} : \mathbf{T} - (I_1)^2 \right] \quad I_3 = \det \mathbf{T}$$

and

$$\mathbf{m} = -\frac{a}{F} \left[ \hat{\mathbf{T}} + \hat{\mathbf{T}}^* - \frac{\hat{\mathbf{T}}}{3} \left( \frac{6 \hat{\mathbf{T}} : \hat{\mathbf{T}} - 1}{(F/a)^2 + \hat{\mathbf{T}} : \hat{\mathbf{T}}} \right) \right] \quad (15)$$

in which:

$$\hat{\mathbf{T}}^* = \hat{\mathbf{T}} - \frac{\mathbf{1}}{3} \quad F = \sqrt{\frac{1}{8} \tan^2 \psi + \frac{2 - \tan^2 \psi}{2 + \sqrt{2} \tan \psi \cos 3\theta}} - \frac{1}{2\sqrt{2}} \tan \psi \quad (16)$$

$$\tan \psi = \sqrt{3} \|\hat{\mathbf{T}}^*\| \quad \cos 3\theta = -\sqrt{6} \frac{\text{tr}(\hat{\mathbf{T}}^* \cdot \hat{\mathbf{T}}^* \cdot \hat{\mathbf{T}}^*)}{(\hat{\mathbf{T}}^* : \hat{\mathbf{T}}^*)^{3/2}} \quad (17)$$

Finally, the scalars  $a$ ,  $\alpha$ ,  $c_1$  and  $c_2$  are given as functions of the material parameters  $\varphi_c$ ,  $\lambda^*$ ,  $\kappa^*$  and  $r$  by the following relations:

$$a = \frac{\sqrt{3}(3 - \sin \varphi_c)}{2\sqrt{2} \sin \varphi_c} \quad \alpha = \frac{1}{\ln 2} \ln \left[ \frac{\lambda^* - \kappa^* S_i}{\lambda^* + \kappa^* S_i} \left( \frac{3 + a^2}{a\sqrt{3}} \right) \right] \quad (18)$$

$$c_1 = \frac{2(3 + a^2 - 2^\alpha a \sqrt{3})}{9rS_i} \quad c_2 = 1 + (1 - c_1) \frac{3}{a^2} \quad (19)$$

Evolution of the state variables  $e$  (void ratio) and  $s$  (sensitivity) is governed by

$$\dot{e} = (1 + e) \text{tr } \mathbf{D} \quad (20)$$

$$\dot{s} = -\frac{k}{\lambda^*} (s - s_f) \sqrt{(\dot{e}_v)^2 + \frac{A}{1 - A} (\dot{e}_s)^2} \quad (21)$$

where  $\dot{e}_v = \text{tr } \mathbf{D}$  and  $\dot{e}_s = \sqrt{2/3} \|\text{dev } \mathbf{D}\|$ .

The basic hypoplastic model requires five constitutive parameters, namely  $\varphi_c$ ,  $\lambda^*$ ,  $\kappa^*$ ,  $N$  and  $r$ , state is characterised by the Cauchy stress  $\mathbf{T}$  and void ratio  $e$ .

	$\varphi_c$	$\lambda^*$	$\kappa^*$	$N$	$r$	$k$	$A$	$s_f$
London clay	22.6°	0.11	0.016	1.375	0.4	-	-	-
Pisa clay	21.9°	0.14	0.0075	1.56	0.3	0.4	0.1	1

Table 1: *Typical parameters of the hypoplastic model for clays.*

An extended model allows us to take into account the effects of meta-stable structure of natural clays. This extension requires three additional parameters ( $k$ ,  $A$ ,  $s_f$ ), and one additional state variable  $s$ . A basic model without the structure effects is recovered if  $s = s_f = 1$  and  $A \neq 1$ . The  $s$  should be always greater or equal to 1.

The basic law parameters should be specified in **group\_materi\_plasti\_hypo\_masin**. The extended parameters for the structure should be specified in **group\_materi\_plasti\_hypo\_masin\_structure**. The hypoplastic history variables,  $e$  for this basic model, and  $e$  and  $s$  for the extended model, should be initialised with **materi\_plasti\_hypo\_history**. As an alternative to specify the  $e$  you can specify the OCR at the start of the calculation in **group\_materi\_plasti\_hypo\_masin\_ocr** (which is used to determine the initial  $e$  via  $e = \exp(N - \lambda^* \ln(|OCR|) - \lambda^* \ln(|p/p_r|)) - 1$ ).

#### Masin clay law

This law is an improved version of the Masin law of the previous section. This law is formulated in kPa, so you should use that as units in your input file.

Anisotropy of sedimentary clays is such a significant feature of their mechanical behaviour that it cannot be ignored in finite element calculations. The hypoplastic model for clays with explicit formulation of the asymptotic state boundary surface is combined with an anisotropic form of the stiffness tensor. The resulting model predicts correctly the very small strain stiffness anisotropy. Anisotropy influences the undrained stress path, and this model is able to model such influence. For theoretical background see [13] and [14].

User input can be defined with the following records: **control\_materi\_plasti\_hypo\_masin\_clay\_ocr\_appl**.

A final notice: this law only functions well if the OCR does not become below 1. If Tochnog detects a void ratio violating this condition, it will automatically change the void ratio in such a way that the OCR becomes 1, and the calculation can continue.

#### Wolffersdorff law

The law proposed by WOLFFERSDORFF [19] is used.

$$\dot{\sigma}_{ij} = L_{ijkl}\dot{\epsilon}_{ij} + f_d N_{ij} \sqrt{\dot{\epsilon}_{kl}\dot{\epsilon}_{kl}} = L_{ijkl}(d_{kl} - f_d Y m_{kl} ||d||)$$

Here the part with  $L_{ijkl}$  gives a linear relation between strain rates and stress rates and the part with  $N_{ij}$  gives a nonlinear relation. The constitutive tensors  $L_{ijkl}$  and  $f_d N_{ij}$  are functions of the effective stress tensor  $\sigma_{ij}$  and void ratio  $e$ . In the above  $d$  denotes the strain rate tensor  $\epsilon$ ,  $Y$  denotes the degree of nonlinearity  $Y = ||L^{-1} : N||$  and the flowrule  $m$  is defined by  $m = -(L^{-1} : N)^{\rightarrow}$  where a  $\rightarrow$  denotes euclidian normalisation.

$$\begin{aligned}
L_{ijkl} &= f_b f_e \frac{1}{\hat{\sigma}_{mn} \hat{\sigma}_{mn}} \hat{L}_{ijkl} \\
N_{ij} &= f_b f_e \frac{F a}{\hat{\sigma}_{kl} \hat{\sigma}_{kl}} (\hat{\sigma}_{ij} + \hat{\sigma}_{ij}^*) \\
\text{and } \hat{\sigma}_{ij} &= \sigma_{ij} / (\sigma_{mn} \delta_{mn}) \quad , \quad \hat{\sigma}_{ij}^* = \hat{\sigma}_{ij} - \frac{1}{3} \delta_{ij} \quad , \quad I_{ijkl} = \delta_{ik} \delta_{jl} \quad , \\
a &= \frac{\sqrt{3}(3 - \sin \varphi_c)}{2\sqrt{2} \sin \varphi_c} \\
F &= \sqrt{\frac{1}{8} \tan^2 \psi + \frac{2 - \tan^2 \psi}{2 + \sqrt{2} \tan \psi \cos 3\theta}} - \frac{1}{2\sqrt{2}} \tan \psi \quad , \\
\tan \psi &= \sqrt{3} \sqrt{\hat{\sigma}_{ij}^* \hat{\sigma}_{ij}^*} \quad , \quad \cos 3\theta = -\sqrt{6} \frac{\hat{\sigma}_{ij}^* \hat{\sigma}_{jk}^* \hat{\sigma}_{ki}^*}{[\hat{\sigma}_{mn}^* \hat{\sigma}_{mn}^*]^{3/2}} \quad .
\end{aligned}$$

For the  $\hat{L}_{ijkl}$  above we have:

$$\hat{L}_{ijkl} = (F^2 I_{ijkl} + a^2 \hat{\sigma}_{ij} \hat{\sigma}_{kl})$$

For  $\hat{\sigma}_{ij}^* = 0$  is  $F = 1$ .

The scalar factors  $f_b$ ,  $f_e$  and  $f_d$  take into account the influence of mean pressure and density:

$$f_b = \frac{h_s}{n} \left( \frac{e_{i0}}{e_{c0}} \right)^\beta \frac{1 + e_i}{e_i} \left( -\frac{\sigma_{ij}\delta_{ij}}{h_s} \right)^{1-n} \left[ 3 + a^2 - a\sqrt{3} \left( \frac{e_{i0} - e_{d0}}{e_{c0} - e_{d0}} \right)^\alpha \right]^{-1},$$

$$f_d = \left( \frac{e - e_d}{e_c - e_d} \right)^\alpha.$$

and  $f_e = \left( \frac{e_c}{e} \right)^\beta$ .

Three characteristic void ratios –  $e_i$  (during isotropic compression at the minimum density),  $e_c$  (critical void ratio) and  $e_d$  (maximum density) – decrease with mean stress:

$$\frac{e_i}{e_{i0}} = \frac{e_c}{e_{c0}} = \frac{e_d}{e_{d0}} = \exp \left[ - \left( -\frac{\sigma_{ij}\delta_{ij}}{h_s} \right)^n \right]$$

The range of admissible void ratios is limited by  $e_i$  and  $e_d$ . The model parameters can be found in Tab. 2. They correspond to Hochstetten sand from the vicinity of Karlsruhe, Germany [19].

$\varphi$ [°]	$h_s$ [MPa]	$n$	$e_{c0}$	$e_{d0}$	$e_{i0}$	$\alpha$	$\beta$
33	1000	0.25	0.95	0.55	1.05	0.25	1.0

Table 2: *Basic hypoplastic parameters of Hochstetten sand.*

The basic law parameters should be specified in **group\_materi\_plasti\_hypo\_wolffersdorff**. The hypoplastic history variables should be initialised with **materi\_plasti\_hypo\_history**.

#### Wolffersdorff law - extended Niemunis version

An extended version of this hypoplastic law is given in [16]. An extra term is added to  $\hat{L}_{ijkl}$ , in index notation:

$$b^2(\delta_{ik}\delta_{jl} - \frac{1}{3}\delta_{ij}\delta_{kl})$$

Here  $b^2$  is given in [16], depending on the input parameter  $\nu$ , which can be seen as the classical Poisson ratio, typically 0.2 or 0.3. The first part of  $f_d$  is determined:

$$\text{if } e \geq e_d \text{ then } f_d = \left( \frac{e - e_d}{e_c - e_d} \right)^\alpha$$

$$\text{if } e < e_d \text{ then } f_d = - \left( \frac{e_d - e}{e_c - e_d} \right)^\alpha$$

Then  $\bar{f}_d$  is determined:

$$\bar{f}_d \text{ equation 4.221 in [16]}$$

where

$$M_e^{(d)} \text{ and } M_T^{(d)} \text{ equation 4.211 in [16]}$$

Finally  $f_d$  is checked

$$\text{if } (f_d < 1) \text{ then } f_d := f_d + (1 - f_d)^z \bar{f}_d$$

where  $z$  is an input parameter specified, typically 5.

You need to specify the parameters  $\nu$  and  $z$  in **group\_materi\_plasti\_hypo\_wolffersdorff\_niemunis**.

#### Wolffersdorff pressure dependent initial void ratio extension

You can correct the initial void ratio  $e_0$ , as specified in the initial value for the history variable in the **node\_dof** records, for the initial pressure to obtain a corrected initial void ratio  $e$ .

$$\frac{e}{e_0} = \exp \left[ - \left( - \frac{\sigma_{ij} \delta_{ij}}{h_s} \right)^n \right]$$

See the basic law description for the parameters  $h_s$  and  $n$ . The  $\sigma_{ij}$  denotes the effective stress tensor (total stresses minus any groundflow pressure). This pressure dependent initial void ratio correction can be activated by **control\_materi\_plasti\_hypo\_pressure\_dependent\_void\_ratio**. After the initial void ratio has been established, the development of the void ratio is governed by volumetric compression or extension of the granular skeleton.

#### Niemunis visco law

For visco hypoplasticity with intergranular strains the stress rate reads:

$$\dot{\sigma}_{ij} = M_{ijkl} \dot{\epsilon}_{kl} - L_{ijkl} \dot{\epsilon}_{kl}^{vis}$$

For visco hypoplasticity the  $L_{ijkl}$  reads:

$$L_{ijkl} = f_b \hat{L}_{ijkl}$$

where

$$f_b = \frac{-\sigma_{kk}}{(1 + a^2/3)\kappa}$$

where  $\kappa$  is a user specified material constant  $\kappa$  (= Butterfield's swelling index upon isotropic unloading), and  $a$  relates to the user specified residual (=critical) friction angle  $\varphi_c$  as:

$$a = \frac{\sqrt{3}(3 - \sin \varphi_c)}{2\sqrt{2} \sin \varphi_c}$$

The pressure normalised stiffness is:

$$\hat{L}_{ijkl} = F^2 I_{ijkl} + a^2 \hat{\sigma}_{ij} \hat{\sigma}_{kl} + b^2 (I_{ijkl} - \frac{1}{3} I_{ikjl})$$

where

$$b^2 = \frac{(1 + \frac{1}{3}a^2)(1 - 2\nu)}{1 + \nu} - 1$$

Notice that the equation for  $b$  only holds true for non-negative right-hand-side, so that puts limits on the allowed values for  $\varphi_c$  and  $\nu$ .

For visco hypoplasticity the  $M_{ijkl}$  reads:

$$\begin{aligned} M_{ijkl} &= [\rho^x m_T + (1 - \rho^x) m_R] L_{ijkl} + \\ &+ \begin{cases} \rho^x (1 - m_T) L_{ijmn} \hat{S}_{mn} \hat{S}_{kl} & \text{for } \hat{S}_{ij} \dot{\epsilon}_{ij} > 0 \\ \rho^x (m_R - m_T) L_{ijmn} \hat{S}_{mn} \hat{S}_{kl} & \text{for } \hat{S}_{ij} \dot{\epsilon}_{ij} \leq 0 \end{cases} \end{aligned}$$

where  $\hat{S}$  intergranular strains are the same as in the formulation without viscosity.

The viscosity strain rate is assumed to be:

$$\dot{\epsilon}_{ij}^{vis} = D_r \hat{m}_{ij} \left( \frac{1}{OCR} \right)^{\frac{1}{I_v}}$$

where the normalised flow rule  $\hat{m}_{ij}$  is

$$\hat{m}_{ij} = \frac{m_{ij}}{\sqrt{m_{ij} m_{ij}}}$$

with

$$m_{ij} = - \left[ \frac{F^2}{a^2} (\hat{\sigma}_{ij} + \hat{\sigma}_{ij}^*) + \hat{\sigma}_{kl} \hat{\sigma}_{kl} \hat{\sigma}_{ij}^* - \hat{\sigma}_{ij} \hat{\sigma}_{kl} \hat{\sigma}_{kl}^* \right]$$

The over-consolidation ratio OCR appearing in the expression for the viscous creep rate is a function of the effective stress  $\sigma_{ij}$  and of the void ratio  $e$

$$OCR = \frac{p_e}{p_e^+}$$

wherein the void ratio is hidden in the equivalent pressure  $p_e$  and  $p_e^+$  is a special stress invariant.

The equivalent pressure  $p_e$  is calculated from

$$\ln \left( \frac{1 + e_{e0}}{1 + e} \right) = \lambda \ln \left( \frac{p_e}{p_{e0}} \right)$$

with a user specified material constant  $\lambda$  (= Butterfield's first compression index) and also user-specified reference parameters  $e_{e0}$ ,  $p_{e0}$  which describe any pair of the void ratio and the effective pressure registered upon an isotropic  $D_r$ -isotach, i.e. during an isotropic first (= virgin) compression test with a constant volumetric rate of deformation equal to  $-\sqrt{3} D_r \frac{\lambda}{\lambda - \kappa}$ .

The stress invariant  $p_e^+$  is calculated using

$$p_e^+ = \begin{cases} \frac{p}{\beta_R - 1} \left[ \beta_R \sqrt{1 + \eta^2 (\beta_R^2 - 1)} - 1 \right] & \text{if } \eta < 1 \\ p(1 + \eta^2)^{\frac{1 + \beta_R}{2}} & \text{otherwise} \end{cases}$$

wherein

$$\eta = q/(Mp) \quad \text{and} \quad M = \frac{6F \sin \varphi_c}{3 - \sin \varphi_c}$$

where  $p = -\sigma_{kk}/3$  and  $q = \sqrt{\frac{3}{2}\sigma_{kl}^*\sigma_{kl}^*}$  are the popular Roscoe's stress invariants. and  $\beta_R$  (= flattening factor for the Rendulic's cap) are the user supplied material constants.

You can specify an initial value of the void ration  $e_0$  in **-hyhis0** with **control\_reset\_dof**. Then the OCR can be calculated with the above equations. As an alternative you can specify the OCR at the start of the calculation in **group\_materi\_plasti\_hypo\_niemunis\_visco\_ocr**; then the initial void ratio will be calculated as follows:  $p_e^+$  will be determined from the equation above, then  $p_e$  is determined from  $p_e = \text{OCR}p_e^+$  and then the initial void ratio  $e_0$  is determined from  $e_0 = (1 + e_e0) * (p_e/p_{e0})^{-\lambda} - 1$ . (reference: Niemunis communications). Application of the specified OCR is triggered by **control\_materi\_plasti\_hypo\_niemunis\_visco\_ocr\_apply**.

User parameters should be specified in **group\_materi\_plasti\_hypo\_niemunis\_visco**.

#### Cohesion extension

A simplistic approach to include cohesion is used here. Instead of feeding the real effective stress state  $\sigma_{ij}$  into the hypoplastic law, an alternative effective stress state  $\sigma_{ij}^c$  is used. Cohesion is modeled by subtracting in each of the normal stress components a value  $c$  representing cohesion:  $\sigma_{11}^c = \sigma_{11} - c$ ,  $\sigma_{22}^c = \sigma_{22} - c$  and  $\sigma_{33}^c = \sigma_{33} - c$ . The shear stresses are not altered:  $\sigma_{12}^c = \sigma_{12}$ , etc.

The cohesion value should be specified in **group\_materi\_plasti\_hypo\_cohesion**.

#### Intergranular strains extension

In order to take into account the recent deformation history, an additional tensorial state variable  $S_{ij}$ <sup>1</sup> is introduced.

Denoting the normalized magnitude of  $S_{ij}$

$$\rho = \frac{\sqrt{S_{ij}S_{ij}}}{R}$$

( $R$  is a material parameter) and the direction of  $S_{ij}$

$$\hat{S}_{ij} = \frac{S_{ij}}{\sqrt{S_{kl}S_{kl}}}$$

( $\hat{S}_{ij} = 0$  for  $S_{ij} = 0$ ), the evolution equation for the intergranular strain tensor reads:

$$\dot{S}_{ij} = \begin{cases} (I_{ijkl} - \rho^{\beta_r} \hat{S}_{ij} \hat{S}_{kl}) \dot{\epsilon}_{kl} & \text{for } \hat{S}_{ij} \dot{\epsilon}_{ij} > 0 \\ \dot{\epsilon}_{ij} & \text{for } \hat{S}_{ij} \dot{\epsilon}_{ij} \leq 0 \end{cases},$$

where  $\dot{S}_{ij}$  is the objective rate of intergranular strain. Rigid body rotations are treated elsewhere (see the section on memory). From the evolution equation (2.2.4) it follows that  $\rho$  must remain between 0 and 1.

---

<sup>1</sup>  $S_{ij}$  is denoted  $\delta_{ij}$  in the paper [15]. However, in order to avoid confusion with Kronecker delta, another symbol is used here.

The general stress-strain relation is now written as

$$\dot{\sigma}_{ij} = M_{ijkl} \dot{\epsilon}_{kl} \quad .$$

The fourth order tensor  $M_{ijkl}$  represents the incremental stiffness and is calculated from the hypoplastic tensors  $L_{ijkl}$  and  $N_{ij}$  which may be modified by scalar multipliers  $m_T$  and  $m_R$ , depending on  $\rho$  and on the product  $\hat{S}_{ij} \dot{\epsilon}_{ij}$ :

$$\begin{aligned} M_{ijkl} = & [\rho^\chi m_T + (1 - \rho^\chi) m_R] L_{ijkl} + \\ & + \begin{cases} \rho^\chi (1 - m_T) L_{ijmn} \hat{S}_{mn} \hat{S}_{kl} + \rho^\theta f_d N_{ij} \hat{S}_{kl} & \text{for } \hat{S}_{ij} \dot{\epsilon}_{ij} > 0 \\ \rho^\chi (m_R - m_T) L_{ijmn} \hat{S}_{mn} \hat{S}_{kl} & \text{for } \hat{S}_{ij} \dot{\epsilon}_{ij} \leq 0 \end{cases} \end{aligned}$$

$\chi$  and  $\theta$  are additional material parameters.

An example intergranular parameters can be found in Tab. 3.

$R$	$m_R$	$m_T$	$\beta_r$	$\chi$	$\theta$
$1 \cdot 10^{-4}$	5.0	2.0	0.50	6.0	6.0

Table 3: *Example of Intergranular hypoplastic parameters.*

The intergranular parameters should be specified in **group\_materi\_plasti\_hypo\_strain\_intergranular**. Additionally you need to include **materi\_strain\_intergranular** in the initialisation part.

The additional parameter theta is very important only for the accumulation of permanent displacements or pore pressures in cyclic or dynamic analysis with small strains. For monotonic loading or higher strains theta is not very important. And thus for such monotonic loading or higher strains you should take  $\theta = \chi$ .

#### ISA-Intergranular strains extension

Author: William Fuentes

The ISA plasticity [6] stands from Intergranular Strain Anisotropy and refers to a mathematical platform which allows to formulate new constitutive models or to extend existing hypoplastic models for soils. This family of models enables the simulation of small strain effects, such as the increase of stiffness and the reduction of the plastic accumulation under repetitive loops. Similar to the original intergranular strain concept by Niemunis and Herle (1996), it allows to couple existing hypoplastic relations to extend their capabilities for cyclic loading. However, the ISA plasticity contrasts with the previous formulation with the incorporation of an elastic locus related to a specific strain amplitude. This new feature makes its formulation elastoplastic, but the yield surface is now defined within the intergranular strain space.

The general stress-strain relation is now written according to:

$$\sigma_{ij} = M_{ijkl} \dot{\epsilon}_{kl}$$

whereby  $M_{ijkl}$  is the stiffness tensor. The yield surface  $F$  of the model is defined within the space of the intergranular strain  $S_{ij}$  and distinguishes elastic conditions  $F < 0$  from plastic conditions  $F = 0$ . The formulation of  $M_{ijkl}$  reads:

$$M_{ijkl} = \begin{cases} m(L_{ijkl} + \rho^x f_d N_{ij} \hat{n}_{kl}) & \text{for } F \geq 0 \\ m_R L_{ijkl} & \text{for } F < 0 \end{cases}$$

whereby  $m$ ,  $\rho^x$ ,  $f_d$  and  $m_R$  are scalar factors,  $N_{ij}$  is the non-linear stiffness tensor,  $L_{ijkl}$  is the linear stiffness tensor and  $\hat{n}_{kl}$  is the intergranular strain model flow rule. The ISA model proposes an evolution equation for the intergranular strain  $S_{ij}$  with an elastoplastic formulation:

$$\dot{S}_{ij} = \dot{\epsilon}_{ij} - \dot{\lambda}_H \hat{n}_{ij}$$

whereby  $\dot{\lambda}_H$  is a plastic multiplier ( $\dot{\lambda}_H = 0$  for  $F < 0$ ). The model may be enhanced to capture the plastic accumulation for larger number of cycles with an additional state variable  $\varepsilon_{acc}$ . This variable is able to distinguish between consecutive cycles or non-consecutive cycles [7]:

$$\varepsilon_{acc} = \varepsilon_{acc} + \frac{C_a}{R} (1 - y_h - \varepsilon_{acc}) \sqrt{\Delta \varepsilon_{ij} \Delta \varepsilon_{ij}}$$

The parameter  $C_a$  controls the rate at which the plastic accumulation reduces upon consecutive cycles. The exponent  $\chi$  is increased to  $\chi_{max}$  to produce this effect on the constitutive equation.

Typical parameters are  $\chi_{max} = 20$  and  $C_a = 0.017$ . See also **group\_materi\_plasti\_hypo\_strain\_isa**.

### 2.2.5 Damage

In the presence of **materi\_damage**  $d$ , the **materi\_stress** follows:

$$\sigma_{ij}^{damaged} = (1 - d) \sigma_{ij}^{undamaged}$$

For the damage, the **group\_materi\_damage\_mazars** model is available:

$$d = d_t \alpha^\beta + d_c (1 - \alpha)^\beta$$

where

$$d_t = 1 - (1 - a_t) \frac{\epsilon^0}{\epsilon^{eq}} - a_t e^{-b_t(\epsilon^{eq} - \epsilon^0)}$$

and

$$d_c = 1. - (1 - a_c) \frac{\epsilon^0}{\epsilon^{\text{eq}}} - a_c e^{-b_t(\epsilon^{\text{eq}} - \epsilon^0)}$$

Here  $\epsilon^{\text{eq}}$  contains the positive principal strains. The parameter  $\alpha$  is given by the ratio  $\frac{\epsilon^{\text{eq}}}{\epsilon}$ , where  $\epsilon$  contains the total strains (both negative and positive). The parameter  $\epsilon^0$  is the strain threshold for damage; other material parameters are  $\beta$ ,  $a_t$ ,  $b_t$ ,  $a_c$ ,  $b_c$ . Typically for concrete:

$$1.e-4 < \epsilon^0 < 3.e-4 ; \beta = 1. ; 1 < a_t < 1.5 ; 500 < b_c < 2000 ; 0.7 < a_c < 1.2 ; e^4 < b_t < 5e^4$$

You can combine damage freely with plasticity models or other material behavior.

### 2.2.6 Average stress (hydrostatic compressibility)

An extra average stress contribution on each of  $\sigma_{11}$ ,  $\sigma_{22}$  and  $\sigma_{33}$  is

$$\frac{1}{co} \frac{\partial v_i}{\partial x_i}$$

where  $co$  is the **group\_materi\_elasti\_compressibility**, which should not be 0. This pressure term can e.g. be used to model nearly incompressible fluids. The compressibility contribution should be combined with a contribution for the deviatoric stresses (e.g. **group\_materi\_viscosity**).

### 2.2.7 Undrained groundflow analysis

In case you want to perform an undrained groundflow analysis, but do not want to have both the material velocity and groundflow equations at the same time in system matrix, you can use **group\_materi\_undrained\_capacity**. Then the following equation will be used to determine the total groundwater pressure changes in an element:

$$C \dot{p}_{total} = \frac{\partial v_i}{\partial x_i}$$

which actually is the groundflow storage equation without permeability. The above equation can be solved on an element-by-element level, so that the groundflow hydraulic pressure head and the storage equation do not need to be added to the complete system matrix. The capacity  $C$  should be specified in **group\_materi\_undrained\_capacity**. Results for the pressure in a element will be written to **element\_intpnt\_materi\_undrained\_pressure**. Application of this undrained analysis can be switched off and on with **control\_materi\_undrained\_apply**.

This option is convenient to prevent the need for large, and ill-conditioned, system matrices in coupled soil - groundwater analysis. Typically the computational strategy may be like this:

```

...
(include capacity for undrained analysis in relevant groups)
group _materi _undrained _capacity ...
...
(set the hydraulic pressure heads, and fix them for the remainder of the calculation)
control _reset _dof ...-pres
bounda _dof ...-tpres
...
(solve material displacements in the remainder of the calculation)
control _timesteps ...
control _materi _undrained _apply ... -yes
...

```

The advantage of the above computational strategy is that never a system matrix with both material velocities and groundflow pressures needs to be solved. When solving the remainder of the calculation Tochnog uses the fixed total pressure from the hydraulic pressure heads plus the excessive undrained pressure of the remainder of the calculation as the full total pressure (when determining total stresses from effective stresses plus full total pressure). Alternatively to setting the hydraulic pressure head at the start with the **control \_reset \_dof**, you can also solve the gravity state for hydraulic pressure heads and material displacements (at the expense of a system matrix with both material velocities and groundflow hydraulic pressures in this gravity calculation; but in the gravity calculation only and the remainder of the calculation).

### 2.2.8 Thermal stresses

Temperature rates cause fictitious thermal strain rates

$$-\alpha \dot{T} \delta_{ij} \quad \text{where} \quad \delta_{ij} = 1 \quad \text{if} \quad i = j \quad \text{else} \quad \delta_{ij} = 0$$

where  $\alpha$  is the **group \_materi \_expansion \_linear** coefficient and  $\dot{T}$  is the **condif \_temperature**. These fictitious thermal strain rates in turn lead to stress rates.

### 2.2.9 Hyper elasticity

Hyper elasticity is used to model rubbers. It should be combined with a total Lagrange formulation for the memory of the material (so use **-total** for **group \_materi \_memory**).

The stresses follow from a strain energy function (with  $C_{ij}$  components of the matrix  $C$ , and where  $F$  is the deformation tensor and  $U$  is the stretch tensor following from the polar decomposition of the deformation tensor)

$$2 \frac{\partial W}{\partial C_{ij}}$$

$$C = F^T F = U^T U$$

#### Deviatoric contributions

To obtain a purely deviatoric function, the following strain measures are used (with  $I_1$ ,  $I_2$  and  $I_3$  the first, second and third invariant of the elastic strain matrix  $C$  respectively)

$$J_1 = I_1 I_3^{-\frac{1}{3}} \quad J_2 = I_2 I_3^{-\frac{2}{3}}$$

The **group\_materi\_hyper\_besseling** function reads ( with  $K_1$ ,  $K_2$  and  $\alpha$  user defined constants)

$$W = K_1(J_1 - 3)^\alpha + K_2(J_2 - 3)$$

The **group\_materi\_hyper\_mooney\_blatz\_ko** function reads (with  $G$  and  $\beta$  user defined constants)

$$W = G * 0.5 * (I_1 - 3.0 + (2.0/\beta)(J^{-\beta} - 1.));$$

This Blatz-Ko hyperelastic material hardens in compression, and softens slightly in tension; it models a foamlike rubber.

The **group\_materi\_hyper\_mooney\_rivlin** function reads (with  $K_1$  and  $K_2$  user defined constants)

$$W = K_1(J_1 - 3) + K_2(J_2 - 3)$$

The **group\_materi\_hyper\_neohookean** function reads (with  $K_1$  a user defined constant)

$$W = K_1(J_1 - 3)$$

The **group\_materi\_hyper\_reduced\_polynomial** function reads (with  $K_i$  user defined constants)

$$W = K_i(J_1 - 3)^i$$

where a summation over  $i = 1, 2, \dots$  is applied.

#### Volumetric contributions

First we define  $J = \sqrt{I_3}$ . Then a volumetric part can be added to the strain energy.

The **group\_materi\_hyper\_volumetric\_linear** contribution reads:

$$W = \frac{K}{2}(J - 1)^2$$

The **group\_materi\_hyper\_volumetric\_murnaghan** contribution reads:

$$W = \frac{K}{\beta} \left( \frac{1}{\beta - 1} J^{-\beta} + 1 \right) J$$

The **group\_materi\_hyper\_volumetric\_polynomial** contribution reads:

$$W = \frac{K_i}{2} (J - 1)^{2i}$$

for  $i = 0, 1, \dots$

The **group\_materi\_hyper\_volumetric\_simo\_taylor** contribution reads:

$$W = \frac{K}{2} ((J - 1)^2 + (\ln J)^2)$$

The **group\_materi\_hyper\_volumetric\_ogden** contribution reads:

$$W = \frac{K}{\beta} \left( \frac{1}{\beta} (J^{-\beta} - 1) + \ln J \right)$$

As an example, you can combine the **group\_materi\_hyper\_mooney\_rivlin** energy function with the **group\_materi\_hyper\_volumetric\_linear** so that the total strain energy function becomes:

$$W = K_1(J_1 - 3) + K_2(J_2 - 3) + \frac{K}{2}(J - 1)^2$$

Here the initial shear modulus and bulk modulus are included as:

$$\text{initial shear modulus} = 2(K_1 + K_2)$$

and

initial bulk modulus =  $K$

respectively.

### 2.2.10 Viscoelasticity

Viscoelasticity is modeled with  $n$  parallel **group\_materi\_maxwell\_chain**. Each of the chains contains a spring with stiffness  $E^m$  in line with a dash pot with relaxation time  $t^m$  ( $m$  indicates the  $m$ -th maxwell chain). The viscoelastic stress rate is given by (with  $C_{ijkl}^m$  is the elastic tensor modulus of the  $m$ -th maxwell chain (depending on  $E^m$  and the poisson ratio))

$$\sum_{m=0}^{m=n-1} (C_{ijkl}^m \dot{\epsilon}_{kl}^{\text{elas}} - \frac{\sigma_{ij}^m}{t^m})$$

### 2.2.11 Viscoplasticity

Viscoplasticity is a model for rate-dependent plasticity. Rate dependent plasticity is important for (high-speed) transient plasticity calculations. It should be used in combination with a plasticity law. Viscoplasticity influences the stresses via the plastic strains.

The **group\_materi\_plasti\_visco\_exponential** model reads

$$\dot{\epsilon}_{kl}^{\text{plas}} = \gamma \, p \, e^{\alpha f} \frac{\partial f^{\text{flow}}}{\partial \sigma_{kl}}$$

where  $\gamma$  and  $\alpha$  are material fluidity constants and  $p$  is the pressure. In case the  $\alpha f$  becomes larger than a limit, it is substituted by the limit to prevent the exponent from becoming excessive large. You can set the limit with the **group\_materi\_plasti\_visco\_exponential\_limit** record. This model was first developed for visco-plastic soil behavior.

The **group\_materi\_plasti\_visco\_power** model reads

$$\dot{\epsilon}_{kl}^{\text{plas}} = \eta(f)^p \frac{\partial f^{\text{flow}}}{\partial \sigma_{kl}}$$

where  $\eta$  (fluidity constant), and  $p$  (power) are user specified parameters.

### 2.2.12 Viscosity

The viscous contribution to the total stress is

$$2\nu D_{ij}$$

where

$$D_{ij} = 0.5\left(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i}\right)$$

and divergence is neglected since we only model slightly compressible flows.

#### Viscous heat generation

The viscous energy loss is turned into heat rate per unit volume  $q$ :

$$q = 2\nu D_{ij} D_{ij}$$

See `group_materi_viscosity_heatgeneration`.

## 2.3 Contact analysis

### 2.3.1 Penalty formulation

Attention: the contact algorithm is experimental and needs more testing.

In contact analysis, normal forces  $F_n$  follow from the condition that bodies cannot penetrate each other. Since we use a penalty formulation, the normal force is given by

$$F_n = \lambda u_n$$

where  $u$  is the penetration and  $\lambda$  is called the **contact\_penalty\_velocity** because it generates forces on the velocity dof's. You can also impose **groundflow\_pressure** and **condif\_temperature** contact conditions by specifying the penalty factors **contact\_penalty\_pressure** and **contact\_penalty\_temperature**.

The contact algorithm is presently under development, and not guaranteed to work for all calculations. You must check your results.

### 2.3.2 Friction and frictional heat generation

This normal force leads to a friction force  $F_f$  which equals

$$F_f = \nu F_n$$

where  $\nu$  is the *friction* coefficient (see **contact\_plasti\_friction**). The friction force causes heat generation rate  $Q$ :

$$Q = \eta F_f v_f$$

where  $v_f$  is the slip velocity, and the factor  $\eta$  is a user specified factor which determines which part of the frictional energy loss is transformed into heat ( $\eta$  is between 0 and 1; see **contact\_heat\_generation**).

## 2.4 Ground water flow

### 2.4.1 Storage equation for fully saturated analysis

The equations in this section come from [22]. The hydraulic pressure head  $h$  follows from the storage equation (with infinite stiffness solid particles):

$$c \dot{h} = (k_1^p \frac{\partial^2 h}{\partial x_1^2} + k_2^p \frac{\partial^2 h}{\partial x_2^2} + k_3^p \frac{\partial^2 h}{\partial x_3^2}) + \frac{\partial v_i}{\partial x_i} - \alpha \dot{T} + f$$

Primary dof is the hydraulic pressure head  $h$ , which is initialised with **groundflow\_\_pressure** in the initialisation part, and which gets a label **-pres** in the **node\_\_dof** records. Further notation:  $c$  **group\_\_groundflow\_\_capacity** (storativity);  $k_i^p$  **group\_\_groundflow\_\_permeability** in  $i$ -direction (permeability);  $x_i$  space coordinate;  $v_i$  material velocity (if present);  $\alpha$  **group\_\_groundflow\_\_expansion** is the expansion coefficient of the groundwater for temperature changes. The equation is given for space coordinates following material velocities  $v_i$  (if present). The water mass acceleration (water newton inertia) is neglected in the above equation. See the naming conventions later how to determine the permeability from experimental data.

#### Groundflow velocities

The groundflow velocities, after initializing **groundflow\_\_velocity**, follow from:

$$v_i^g = k_i^p \frac{\partial h}{\partial x_i}$$

#### Total groundwater pressure

The total groundwater pressure, or pore-pressure, is for example needed to calculate the total stresses in soils. The total groundwater pressure follows from:

$$p_{\text{total}} = h - \rho g z$$

where  $g$  is the gravitational acceleration, and  $\rho$  is the **groundflow\_\_density** (Please notice that  $g$  and  $z$  typically are negative numbers).

Tochnog considers pressure a pore pressure of  $p = 0$ , or positive, as indication that there is in fact no water pressure, so the porous soil skeleton is filled with air. In this case, the total soil stress is only composed by the effective stress of the soil skeleton.

The total stress in saturated soils follows from: total soil stress = effective soil stress + total groundwater pressure (pore pressure). This will only be done for isoparametric finite elements which have groundflow data specified.

For non-saturated soil you optionally can specify **groundflow\_\_pressure\_\_factor** such that the total groundwater pressure will be added only with this specified factor.

## Static groundwater pressure

The static pressure due to gravity is:

$$p_{\text{static}} = \rho g \Delta z$$

where the  $\Delta z$  is the distance to the groundwater level, the phreatic level. The phreatic level needs to be specified with the **groundflow\_phreatic\_level** record. Alternatively you can specify **post\_calcul\_static\_pressure\_height** or **post\_calcul\_static\_pressure**. If all of these are not specified, the static pressure cannot be determined, so it remains zero.

## Dynamic groundwater pressure

The dynamic groundwater pressure follows from

$$p_{\text{dynamic}} = p_{\text{total}} - p_{\text{static}}$$

## Boundary conditions

If the groundwater velocity is 0 normal to an edge (say at the interface with a rock layer it is zero), then you should prescribe nothing on that edge (Tochnog will then take care of that boundary conditions for you).

At the phreatic level where the groundflow meets free air the hydraulic pressure head should become  $\rho g z$ . You can either set this yourself by using **bounda\_dof** combined with **bounda\_time** or else demand that Tochnog automatically does it for you by activating the option **groundflow\_phreatic\_bounda**.

At edges where you have some other hydraulic pressure head you need to specify that head yourself with **bounda\_dof** and **bounda\_time** records. If you want to set directly the hydraulic head you need to use **-pres** in **bounda\_dof**, however if you want to set the total pressure (pore pressure) you need to use **-topres** in **bounda\_dof**.

If gravity is not of importance, e.g. in biomechanics where the storage equation is used to model fluid transport in soft tissues, the hydraulic pressure head  $h$  is equal to the total pressure, and thus is zero at edges where the water meets the free air. In this case, set  $h$  to zero by using **bounda\_dof** combined with **bounda\_time**.

## Postprocessing

For all printing, plotting etc. you normally get the hydraulic pressure head  $h$  since it is the primary dof solved in the storage equation. The total pressure, static pressure and dynamic pressure are obtained using the **post\_calcul** option.

## Capacity and permeability explanation

Following conventional naming, we remind the user that the capacity depends on the porosity  $n$  and water compressibility  $\beta$ :

$$c = n \beta$$

and the permeability  $k^p$  used in the storage equation above you can determine from an experiment with

$$k^p = \frac{k_{experiment}}{\rho |g|}$$

where  $k_{experiment}$  is the experimental value in units  $\frac{length}{time}$  (by example  $\frac{m}{s}$  in SI units).

### 2.4.2 Non-saturated analysis

with diagrams

You can perform a non-saturated analysis by making the permeability dependent on the groundwater total pressure (= pore pressure) by a dependency diagram. The diagram accounts for high permeability at saturation and low permeability at non-saturation. For example, do something like:

```
...
dependency _item 10 -group _groundflow _permeability 0 -to _pres 4
dependency _diagram 10 -100. 0.0 0.05 100.
1.e-2 1.e-2 1.e-8 1.e-8
1.e-2 1.e-2 1.e-8 1.e-8
...
...
```

The atmospheric air pressure is 0, so that is where the permeability starts changing it's value in the table. You can also specify a table for **group\_groundflow\_capacity** to model non-saturated capacity.

van Genuchten

As an alternative to specifying diagrams you can use the specific van-Genuchten model for non-saturated ground water flow. The pore-pressure head is defined by

$$\phi_p = -\frac{p}{\rho g}$$

with  $p$  the pore pressure (= total pressure),  $\rho$  the ground water density and  $g$  is the absolute value of the gravity acceleration (typically 9.81). The degree of saturation is a function of the pore-pressure head

$$S = S(\phi_p)$$

The total capacity is the sum of the saturated capacity and a non-saturated part:

$$c = c_{\text{sat}} + n \frac{dS(\phi_p)}{d\phi_p}$$

where  $c_{\text{sat}}$  is the saturated groundflow capacity as specified by **group\_groundflow\_capacity** and  $n$  is the porosity specified by **group\_porosity**. The total permeabilities  $k_i$  are written as a relative factor of the saturated permeabilities

$$k_i = k_{\text{rel}}(S)k_{\text{sat},i}$$

where  $k_i$  is the total permeability in direction  $i$ ,  $k_{\text{rel}}(S)$  is a factor dependent on the saturation  $S$  and  $k_{\text{sat},i}$  is the saturated permeability specified by **group\_groundflow\_permeability**.

Now for the van-Genuchten model we have

$$S(\phi_p) = S_{\text{residu}} + (S_{\text{sat}} - S_{\text{residu}}) (1 + (g_a |\phi_p|)^{g_n})^{(1-g_n)/g_n}$$

which has the following model parameters:  $S_{\text{residu}}$  is the residual saturation,  $S_{\text{sat}}$  normally is 1.0 but may be less than 1.0 if in case of trapped air, and  $g_a$  and  $g_n$  are constants to be determined experimentally. The derivative of this law defines the additional non-saturated capacity as defined above. After definition of the effective saturation  $S_e$

$$S_e = \frac{S - S_{\text{residu}}}{S_{\text{sat}} - S_{\text{residu}}}$$

the relative permeability factor is defined as

$$k_{\text{rel}}(S) = (S_e)^{g_l} \left( 1 - (1 - S_e^{g_n/(g_n-1)})^{(g_n-1)/g_n} \right)^2$$

To use the model you need to specify the saturated parameters **group\_groundflow\_capacity** and **group\_groundflow\_permeability** as usual, specify the porosity in **group\_porosity**, specify specific van-Genuchten parameters in **group\_groundflow\_nonsaturated\_vangenuchten** and initialise **groundflow\_saturation** in the initialisation part.

### 2.4.3 Consolidation analysis

Look in the 'Consolidation' section of the 'Interaction analyzes and advanced analyzes' chapter in the end of this manual on how to perform consolidation analyzes (combined groundwater flow with soil stress analyzes).

In case you have **groundflow\_total\_pressure\_limit** set to 0 and the total pressure is 0, then Tochnog assumes that there is no water so the consolidation part in the equations will also be skipped. In case you have **groundflow\_total\_pressure\_limit** set to a high positive value this will not be done, so the consolidation part will also be used in case the total pressure is 0 (or positive).

## 2.5 Wave equation

$$\frac{\partial \dot{s}}{\partial t} = c^2 \left( \frac{\partial^2 s}{\partial x_1^2} + \frac{\partial^2 s}{\partial x_2^2} + \frac{\partial^2 s}{\partial x_3^2} \right)$$
$$\frac{\partial s}{\partial t} = \dot{s}$$

The primary dof's are the **wave\_scalar**  $s$  and its first time derivative **wave\_fscalar**  $\dot{s}$  (as TOCHNOG only solves first order in time equations, the first time derivative of  $s$  also becomes primary dof in order to turn this second order in time equation into a set of first order in time equations). Further notation:  $x$  space coordinate,  $t$  time and  $c$  speed of sound.

## 2.6 Probabilistic distributions

The section summarises mathematical formulation of the so-called random finite element method, as described, e.g. in [8].

Distribution of a random variable (e.g.,  $C$ ) is controlled by these basic parameters: parameters of the statistical distribution (typically mean value  $\mu_C$  and standard deviation  $\sigma_C$ ) and so-called correlation length  $\theta_C$  that controls spatial variability of variable  $C$ .

Two probabilistic distributions are available in Tochnog: normal distribution and log-normal distribution. Probability function  $P(C)$  of normal distribution is defined as:

$$P(C) = \frac{1}{\sigma_C \sqrt{2\pi}} \exp \left[ -\frac{(C - \mu_C)^2}{2\sigma_C^2} \right] \quad (22)$$

where  $\mu_C$  is a mean value and  $\sigma_C$  is standard deviation. Probability function  $P(C)$  of log-normal distribution is defined as:

$$P(C) = \frac{1}{C \sigma_{\ln C} \sqrt{2\pi}} \exp \left[ -\frac{(\ln C - \mu_{\ln C})^2}{2\sigma_{\ln C}^2} \right] \quad (23)$$

Quantities  $\mu_{\ln C}$  and  $\sigma_{\ln C}$  may be calculated from  $\mu_C$  and  $\sigma_C$  using

$$\sigma_{\ln C} = \sqrt{\ln \left[ 1 + \left( \frac{\sigma_C}{\mu_C} \right)^2 \right]} \quad \mu_{\ln C} = \ln \mu_C - \frac{1}{2} \sigma_{\ln C}^2 \quad (24)$$

### 2.6.1 Generation of random field

A number of different techniques to generate random fields is available (see, e.g., [5]). In this following, the most simple method based on Cholesky decomposition of the correlation matrix.

First, vector  $\mathbf{X}$  of statistically independent random numbers  $x_1, x_2, \dots, x_n$  (where  $n$  is number of elements in the FE mesh) with a standard normal distribution (i.e., with probability function of Eq. (22) with  $\mu_C = 0$  and  $\sigma_C = 1$ ) is generated.

A correlation matrix  $\mathbf{K}$ , which represents the correlation coefficient between each of the element used in the finite element analysis, is assembled. The correlation matrix  $\mathbf{K}$  has the following form:

$$\mathbf{K} = \begin{bmatrix} 1 & \rho_{12} & \dots & \rho_{1n} \\ \rho_{21} & 1 & \dots & \rho_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \rho_{n1} & \rho_{n2} & \dots & 1 \end{bmatrix} \quad (25)$$

where  $\rho_{ij}$  is the correlation coefficient between elements  $i$  and  $j$ , calculated using Markov function:

$$\rho_{ij} = \exp \left[ -\frac{2x_{ij}}{\theta_C} \right] \quad (26)$$

where  $x_{ij}$  is absolute distance between elements  $i$  and  $j$  (distance between centers of gravity of elements  $i$  and  $j$ ). For anisotropic case Eq. (26) reads

$$\rho_{ij} = \exp \left[ -2 \sqrt{\left( \frac{\tau_{xij}}{\theta_{Cx}} \right)^2 + \left( \frac{\tau_{yij}}{\theta_{Cy}} \right)^2 + \left( \frac{\tau_{zij}}{\theta_{Cz}} \right)^2} \right] \quad (27)$$

where  $\theta_{Cx}$  is a correlation coefficient in direction of  $x$ -axis and  $\tau_{xij}$  is a distance between two elements  $i$  and  $j$  in  $x$  direction. The same notation applies for  $y$  and  $z$  directions.

The matrix  $\mathbf{K}$  is positive definite and hence, the standard Cholesky decomposition algorithm can be used to factor the matrix into upper and lower triangular forms,  $\mathbf{S}$  and  $\mathbf{S}^T$ , respectively:

$$\mathbf{S}^T \mathbf{S} = \mathbf{K} \quad (28)$$

The vector of correlated random variables  $\mathbf{G}$  (i.e.,  $G_1, G_2, \dots, G_n$ , where  $G_i$  specifies the random component of variable  $C$  in element  $i$ ) is calculated by

$$\mathbf{G} = \mathbf{S}^T \mathbf{X} \quad (29)$$

Vector  $\mathbf{X}$  is generated as described above.

Finally, value of the variable  $C$  is assigned to each element ( $C_i$ ) by the following transformation:

- for normally distributed variable  $C$ :

$$C_i = \mu_C + \sigma_{CA} G_i \quad (30)$$

where  $\sigma_{CA}$  is calculated from  $\sigma_C$  as described in the following section.

- for log-normally distributed variable  $C$ :

$$C_i = \exp(\mu_{\ln C} + \sigma_{\ln CA} G_i) \quad (31)$$

where  $\mu_{\ln C}$  is calculated by Eq. (24)b using  $\sigma_{\ln CA}$  instead of  $\sigma_{\ln C}$ ;  $\sigma_{\ln CA}$  is calculated from  $\sigma_{\ln C}$  as described in the following section.

### 2.6.2 Local averaging

The input parameters of  $C$  that relate to the mean, standard deviation and spatial correlation length are assumed to be defined at the point level. Due to the finite size of each finite element, point statistical distribution must be averaged over the element. This results in reduced  $\sigma_{\ln C}$  in the case of log-normal distribution and reduced  $\sigma_C$  in the case of normal distribution.  $\mu_{\ln C}$  in the first case and  $\mu_C$  in the second case remain unaffected.

The locally-averaged standard deviations ( $\sigma_{\ln CA}$ ,  $\sigma_{CA}$ ), which are used in Eqns. (30, 31), are calculated from their point values using

$$\sigma_{\ln CA}^2 = \gamma \sigma_{\ln C}^2 \quad \sigma_{CA}^2 = \gamma \sigma_C^2 \quad (32)$$

where  $\gamma$  is the variance reduction factor calculated by integration of the Markov function (26). In 1D for a finite element of side length  $\alpha\theta_C$

$$\gamma = \frac{2}{(\alpha\theta_C)^2} \int_0^{\alpha\theta_C} \exp\left(-\frac{2}{\theta_C}\sqrt{x^2}\right) (\alpha\theta_C - x) dx \quad (33)$$

In 2D for square finite element of side length  $\alpha\theta_C$

$$\gamma = \frac{4}{(\alpha\theta_C)^4} \int_0^{\alpha\theta_C} \int_0^{\alpha\theta_C} \exp\left(-\frac{2}{\theta_C}\sqrt{x^2 + y^2}\right) (\alpha\theta_C - x)(\alpha\theta_C - y) dx dy \quad (34)$$

In 3D for hexahedral finite element of side length  $\alpha\theta_C$

$$\gamma = \frac{8}{(\alpha\theta_C)^6} \int_0^{\alpha\theta_C} \int_0^{\alpha\theta_C} \int_0^{\alpha\theta_C} \exp\left(-\frac{2}{\theta_C}\sqrt{x^2 + y^2 + z^2}\right) (\alpha\theta_C - x)(\alpha\theta_C - y)(\alpha\theta_C - z) dx dy dz \quad (35)$$

For the anisotropic case in 2D:

$$\gamma = \frac{4}{l^4} \int_0^l \int_0^l \exp\left[-2\sqrt{\left(\frac{x}{\theta_{Cx}}\right)^2 + \left(\frac{y}{\theta_{Cy}}\right)^2}\right] (l - x)(l - y) dx dy \quad (36)$$

and for the anisotropic case in 3D:

$$\gamma = \frac{8}{l^6} \int_0^l \int_0^l \int_0^l \exp\left[-2\sqrt{\left(\frac{x}{\theta_{Cx}}\right)^2 + \left(\frac{y}{\theta_{Cy}}\right)^2 + \left(\frac{z}{\theta_{Cz}}\right)^2}\right] (l - x)(l - y)(l - z) dx dy dz \quad (37)$$

In order to calculate the variance reduction due to local averaging correctly, all elements in the mesh should be of the same size and all elements should be regular squares. If irregular elements are used, exact value of  $\gamma$  is in Tochnog approximated by calculation of  $\gamma$  for an equivalent square element using Eq. (35) with area equal to an average area of all elements in the mesh.

The approximate value of  $\gamma$  requires that you use as much as possible elements of the same size and shape in the complete calculation domain.

### 2.6.3 Monte Carlo simulations

The most simple but very powerful technique to solve the probabilistic problem is a Monte Carlo technique. The same problem is solved many times, each time with different fields of random variables generated according to prescribed parameters.

The whole problem is solved in the following steps:

1. Generate random fields according to Sec. 2.6.1 using **control\_distribute** command as many times as many variables are treated as random. In principle, any variable can be related as random. For example material parameters, dof's (e.g., history variables), etc.

2. Solve the problem using finite element method. Collect required results of each Monte Carlo realisation into an output file. The user can prescribe any result to be collected into an output file using **control\_repeat\_save** command (e.g., **time\_current**, final displacement of a selected point, etc.).
3. Repeat items 1. and 2.  $m$ -times, where  $m$  is a prescribed number of Monte Carlo realisations.  $m$  value is specified in Tochnog input file using **control\_repeat** command.
4. Evaluate results statistically. More complex statistical evaluation is done by the user, calculation of mean value and standard deviation can be done in Tochnog using **control\_repeat\_save\_calculate** command.

#### 2.6.4 Input data records

A typical piece of input file could be like this:

```

print_group_data ... (print in the gid files distributed group data so that
you get a plot of it)
...
control_distribute 10 ... (distribute something with correlation in space)
control_distribute_parameters 10 ...
control_distribute_correlation_length 10 ...
control_distribute 20 ... (distribute something else without correlation in
space)
control_distribute_parameters 20 ...
...
control_timestep 30 ... (do timesteps)
control_timestep_iterations_automatic 30 ... (with automatic timestep-
ping)
control_timestep_iterations_automatic_stop 30 -continue (don't abort
the calculation if the minimum step size is reached, e.g. in a stability calcula-
tion)
...
control_print_data_versus_data 40 ... (save data for repeats in a dvd
file)
...
control_repeat 50 100 10 (jump 100 times back to control index 10)
control_repeat_save 50 ... (select results to be saved for each repeat)
control_repeat_save_calculate 50 -yes (perform statistical analysis on
saved results)
...
control_print_gid 100 -yes
control_print 100 -repeat_save_result-repeat_save_calculate_result
...

```

### 3 Input file, general remarks

The input is free format. Comments are enclosed between ( ), e.g. (this is comment only); a comma , is not allowed inside comments. The input should consist of an initialization part and a data part, separated by **end\_initia** and ended by **end\_data**

```
initialization
...
initialization
end_initia
data_item index data_values
...
data_item index data_values
end_data
```

**Bold** printed data in this manual can be used literally. *Italic* printed data is only symbolic (it represents a number or a word).

## 4 Input file, initialization part

The initialization part contains initialization records and an **end\_initia** record

```
initialization
...
initialization
end_initia
```

The example below initializes a solid material

```
echo -yes
number_of_space_dimensions 2
materi_velocity
materi_strain_total
materi_stress
end_initia
```

The **echo** (always the first record), **number\_of\_space\_dimensions** (always the second record), and **end\_initia** record should be supplied always. Use **echo -yes** to echo the input and **echo -no** to not echo the input. Use **number\_of\_space\_dimensions 1** for 1D problems, etc.. The records **materi\_velocity**, **materi\_strain\_total** and **materi\_stress** create a velocity, strain and stress field in the entire domain. In the following sections, all possible *initialization* records are discussed. Most of these records create an doffield, a physical field like a temperature field or a strain field, over the computational domain.

### 4.1 *echo switch* (first record of initialization part)

If *switch* is **-yes** the input will be echoed. If *switch* is **-no** the input will not be echoed. This needs to be the first record.

### 4.2 **number\_of\_space\_dimensions** *number\_of\_space\_dimensions* (second record of initialization part)

Set *number\_of\_space\_dimensions* to 1 in 1D, etc.. This needs to be the second record.

### 4.3 derivatives (third record of initialization part, if specified)

If this record is included, the time derivative and the space derivatives will be stored in the **node\_dof** records. This is only required for a limited number of models. The model description will specify if this **derivatives** initialization is needed.

### 4.4 beam\_rotation

The beam rotations  $\phi_x$ ,  $\phi_y$  and  $\phi_z$  are added to the **node\_dof** records.

Please notice that always all three rotations are included. Typically for a 2D calculation you may want to fix the  $\phi_x$  and  $\phi_y$  to 0, by using a **bounda\_dof** record.

### 4.5 condif\_temperature

The temperature  $T$  is added to the **node\_dof** records.

### 4.6 groundflow\_pressure

The pressure  $p$  is added to the **node\_dof** records.

### 4.7 groundflow\_pressure\_gradient

The gradient of the hydraulic pressure  $\frac{dh}{dx} \frac{dh}{dy} \frac{dh}{dz}$  is added to the **node\_dof** records.

### 4.8 groundflow\_saturation

The groundflow saturation  $S$  is added to the **node\_dof** records.

### 4.9 groundflow\_velocity

The ground water flow velocity  $v_i^g$  is added to the **node\_dof** records.

### 4.10 materi\_damage

The damage  $d$  is added to the **node\_dof** records. Also **materi\_velocity** and **materi\_strain\_total** should be initialized.

#### 4.11 **materi\_\_acceleration**

The accelerations  $a_i$  are added to the **node\_\_dof** records.

#### 4.12 **materi\_\_displacement**

The displacements  $u, v, w$  are added to the **node\_\_dof** records. If **materi\_\_displacement** is initialized, then equations like the convection and diffusion of heat equation or the ground water flow equation are evaluated over the deformed volume, which is the sum of the nodal coordinates plus its displacements. Also if **materi\_\_displacement** is initialized, the total Lagrange model will be used in stress analysis.

Condition: also **materi\_\_velocity** should be initialized because the displacement follows from integration of the velocity.

#### 4.13 **materi\_\_displacement\_\_relative**

Displacement relative to a previous point in the calculation. These are the current displacements minus the displacements before these were changed with timesteps in **control\_\_timestep** or a displacement reset in **control\_\_reset\_\_dof**.

For example, this option comes handy when you want to understand the extra displacements caused by the last timesteps.

#### 4.14 **materi\_\_history\_\_variable** *number\_of\_variables*

Generic history variables which can e.g. be used in some user supplied routines or otherwise.

#### 4.15 **materi\_\_maxwell\_\_stress** *number\_of\_chains*

Maxwell stress  $\sigma_{11}^m \sigma_{12}^m \sigma_{13}^m \sigma_{22}^m \sigma_{23}^m \sigma_{33}^m$  is added to the **node\_\_dof** records. The parameter *number\_of\_chains* should match data item **group\_\_mater\_i\_\_maxwell\_\_chain**. The number of maxwell stresses is  $6 * \text{number\_of\_chains}$ .

#### 4.16 **materi\_\_plasti\_\_camclay\_\_history**

The history variables  $e_0$  and  $p_0$  for the camclay plasticity models are added to the **node\_\_dof** records.

#### 4.17 **materi\_plasti\_cap1\_history**

The history variable  $p_c$  for the cap1 plasticity models is added to the **node\_dof** records.

#### 4.18 **materi\_plasti\_diprisco\_history** *number\_of\_history\_variables*

The history variable di Prisco plasticity models are added to the **node\_dof** records. For the **group\_materi\_plasti\_diprisco** model you need to set *number\_of\_history\_variables* to 11. For the **group\_materi\_plasti\_diprisco\_density** model you need to set *number\_of\_history\_variables* to 12.

#### 4.19 **materi\_plasti\_f**

The plastic yield rule  $f$  is added to the **node\_dof** records. This should only be used for elasto-plastic calculations, and not for visco-plastic calculations.

#### 4.20 **materi\_plasti\_f\_nonlocal**

The nonlocal plastic yield rule  $fn$  is added to the **node\_dof** records. See also: **nonlocal**.

#### 4.21 **materi\_plasti\_generalised\_non\_associate\_cam\_clay\_for\_bonded\_soils\_his**

The history variables for the Generalised Non Associate Cam Clay for Bonded Soils plasticity model are added to the **node\_dof** records.

#### 4.22 **materi\_plasti\_hardsoil\_history**

The history variable  $abs(p)$  for the hardsoil plasticity model is added to the **node\_dof** records. It contains the maximum pressure history.

#### 4.23 **materi\_plasti\_hypo\_history**

Eight history variables for the hypo-plasticity models are added to the **node\_dof** records.

The first history variable **-hyhis0** contains the void ratio, and should be initialized by initially specifying **node\_dof** records, or optionally specifying an OCR value with a **group\_materi\_plasti\_hypo..** record.

The second history variable **-hyhis1** will be filled with the time step size of the hypoplastic substepping scheme; this is meant for postprocessing only.

The third history variable **-hyhis2** will be filled with the mobilized friction angle in degrees; this is meant for postprocessing only.

The fourth history variable **-hyhis3** will be filled with the a measure of the effective stiffness following from the hypoplasticity law (  $\sqrt{M_{ijkl}M_{ijkl}}$  ); this is meant for postprocessing only.

The fifth history variable **-hyhis4** for all laws with the structure option, will be filled with the structure variable  $s$  and should be initialized by initially specifying **node\_\_dof** records.

The sixth history variable **-hyhis5**, will be filled with the  $OCR$  value; this is meant for post-processing only. This is only available for the **group\_\_materi\_\_plasti\_\_hypo\_\_masin\_\_clay** and **group\_\_materi\_\_plasti\_\_hypo\_\_niemunis\_\_visco** laws.

The seventh history variable **-hyhis6** for the **group\_\_materi\_\_plasti\_\_hypo\_\_wolffersdorff**, will be filled with the density index  $I_d = \frac{ec-e}{ec-ed}$ ; this is meant for postprocessing only.

The eight history variable **-hyhis7** for hypoplasticity laws with intergranular strains, will be filled with the intergranular strain variable  $\rho$ ; this is meant for postprocessing only.

#### 4.24 materi\_\_plasti\_\_kappa

The size of the plastic strain  $\kappa$  is added to the **node\_\_dof** records. See the theory section.

#### 4.25 materi\_\_plasti\_\_kappa\_\_shear

The size of the shear part of the plastic strain  $\kappa^{shear}$  is added to the **node\_\_dof** records. See the theory section.

#### 4.26 materi\_\_plasti\_\_phimob

The mobilized friction angle  $\phi_{mob}$  is added to the **node\_\_dof** records. It is defined as the angle, in radians, for which the yield function

$$f = 0.5(\sigma_2 - \sigma_0) + 0.5(\sigma_2 + \sigma_0) * \sin(\phi_{mob}) - c\cos(\phi_{mob})$$

becomes zero. This is available for mohr-coulomb plasticity only. Please realise that in regions with substantial cohesion the mobilized friction angle  $\phi_{mob}$  can exceed the friction angle  $\phi$  from the plasticity law. In case of zero cohesion, or cohesion small relative to the stresses, yield is reached if the  $\phi_{mob}$  reaches the friction angle  $\phi$ . The definition above can give either negative or positive values for  $\phi_{mob}$ ; negative values simply indicate that the stress state is far away from yielding. The **phimob** is calculated in degrees.

#### 4.27 `materi_plasti_rho`

The plastic kinematic hardening vector  $\rho_{11} \ \rho_{12} \ \rho_{13} \ \rho_{22} \ \rho_{23} \ \rho_{33}$  is added to the **node\_dof** records. See also **group\_materi\_plasti\_kinematic\_hardening**.

#### 4.28 `materi_strain_energy`

The material strain energy  $0.5\sigma_{ij}\epsilon_{ij}^{\text{elas}}$  is added to the **node\_dof** records. You can print or plot it to see where energy is stored after loading. Also **materi\_stress** and **materi\_strain\_elasti** should be initialised.

#### 4.29 `materi_strain_elasti`

The elastic strain  $\epsilon_{kl}^{\text{elas}}$  is added to the **node\_dof** records. See also: **materi\_strain\_total**.

#### 4.30 `materi_strain_intergranular`

The intergranular strain  $S_{ij}$  is added to the **node\_dof** records. This can be used by hypoplasticity laws, see the theory section.

#### 4.31 `materi_strain_isa_c`

The ISA intergranular back-strain  $C_{ij}$  is added to the **node\_dof** records. This can be used by hypoplasticity laws with ISA-intergranular strains, see the theory section.

#### 4.32 `materi_strain_isa_eacc`

The ISA intergranular accumulated-strain  $\epsilon_{acc}$  is added to the **node\_dof** records. This can be used by hypoplasticity laws with ISA-intergranular strains, see the theory section.

#### 4.33 `materi_strain_plasti`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  is added to the **node\_dof** records. See also: **materi\_strain\_total**.

#### 4.34 `materi_strain_plasti_camclay`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  specifically for the camclay model is added to the `node_dof` records. See also: `materi_strain_plasti`.

#### 4.35 `materi_strain_plasti_cap`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  specifically for cap models is added to the `node_dof` records. See also: `materi_strain_plasti`.

#### 4.36 `materi_strain_plasti_compression`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  specifically for the compression model is added to the `node_dof` records. See also: `materi_strain_plasti`.

#### 4.37 `materi_strain_plasti_diprisco`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  specifically for the diprisco model is added to the `node_dof` records. See also: `materi_strain_plasti`.

#### 4.38 `materi_strain_plasti_generalised_non_associate_cam_clay_for_bonded_s`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  specifically for the generalised non associate cam clay for bonded soils model is added to the `node_dof` records. See also: `materi_strain_plasti`.

#### 4.39 `materi_strain_plasti_druckprag`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  specifically for the drucker-prager model is added to the `node_dof` records. See also: `materi_strain_plasti`.

#### 4.40 `materi_strain_plasti_hardsoil`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  specifically for the hardsoil model is added to the `node_dof` records. See also: `materi_strain_plasti`.

#### 4.41 `materi_strain_plasti_mohr_coul`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  specifically for the mohr\_coulomb models is added to the **node\_dof** records. See also: `materi_strain_plasti`.

#### 4.42 `materi_strain_plasti_tension`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  specifically for the tension model is added to the **node\_dof** records. See also: `materi_strain_plasti`.

#### 4.43 `materi_strain_plasti_vonmises`

The plastic strain  $\epsilon_{kl}^{\text{plas}}$  specifically for the von-mises model is added to the **node\_dof** records. See also: `materi_strain_plasti`.

#### 4.44 `materi_strain_total`

The total strain  $\epsilon_{kl}$  is added to the **node\_dof** records. All strains are time integrals of the strain rates for a specific material particle which happens to be present in the node.

#### 4.45 `materi_strain_total_kappa`

The maximum strain size is added to the **node\_dof** records.

#### 4.46 `materi_strain_total_compression_kappa`

The maximum principal compression total strain as occurred in history is added to the **node\_dof** records.

#### 4.47 `materi_strain_total_shear_kappa`

The maximum size of the deviatoric part of the total strain as occurred in history is added to the **node\_dof** records.

#### 4.48 **materi\_strain\_total\_tension\_kappa**

The maximum principal tensional total strain as occurred in history is added to the **node\_dof** records.

#### 4.49 **materi\_stress**

The stresses  $\sigma_{11}$   $\sigma_{12}$   $\sigma_{13}$   $\sigma_{22}$   $\sigma_{23}$   $\sigma_{33}$  are added to the **node\_dof** records.

#### 4.50 **materi\_stress\_pressure\_history**

The maximum of the absolute value of the pressure which occurs over time is added to the **node\_dof** records. See also **group\_materi\_elasti\_stress\_pressure\_history\_factor** in the data part.

#### 4.51 **materi\_velocity**

The velocities  $v_i$  are added to the **node\_dof** records.

#### 4.52 **materi\_velocity\_integrated**

The integrated velocities  $vi_i$  are added to the **node\_dof** records. The integration of nodal velocities in fact results in displacements. But asking for these integrated velocities doesn't activate automatically that the calculation is done over the total deformed volume (as is the case when you initialize **materi\_displacement**), and not automatically a total Lagrange model is used in stress analysis.

#### 4.53 **materi\_void\_fraction**

The material void fraction  $f^*$  is added to the **node\_dof** records. This is required for the **group\_materi\_plasti\_gurson** model.

#### 4.54 **materi\_work**

The material second order work  $\dot{\sigma}_{ij}\dot{\epsilon}_{ij}$  is added to the **node\_dof** records. You can print or plot it to see where material instabilities are present.

#### 4.55 **mrang** *maximum\_range\_length*

Sets the maximum length of ranges **-ra** . . . **-ra**.

#### 4.56 **mstring** *maximum\_number\_of\_strings*

Sets the maximum number of strings in a define block.

#### 4.57 **wave\_scalar**

Scalar in wave equation is **node\_\_dof** records. Condition: also **wave\_\_fscalar** should be initialized.

#### 4.58 **wave\_fscalar**

The first time derivative in the wave equation is added to the **node\_\_dof** records. Condition: also **wave\_\_scalar** should be initialized.

#### 4.59 **end\_\_initia** (last record of initialization part)

## 5 Input file, data part, introduction

Data items in the data part are used to control the calculation, select required output, give dof's initial values, etc.. Note that an **end\_data** record is needed.

```
data_item index data_values
...
data_item index data_values
end_data
```

Consider the following example

```
element 0 -tria3 0 1 2
element 1 -tria3 1 2 3
node 0 0. 0.
node 1 1. 0.
node 2 0. 1.
node 3 1. 1.
...
end_data
```

Note that the data items **element** and **node** are indexed. In fact most data items need to be indexed. Indexing starts at 0 (all numbering in TOCHNOG starts at 0). Indices need not strictly be sequential (e.g. only the indices 1,2 and 5 of a data item may be specified).

The following sections first treat some extras that can be used in the data part. After that, all possible data items are specified.

### Arithmetic blocks

You also can use the arithmetic expressions **plus**, **minus**, **multiply** and **divide**. We show some examples:

```
(make A equal to 4.1)
start_arithmetic
A 1.1 plus 3
end_arithmetic
...
(make B equal to 3.2)
start_arithmetic
B 3.2
```

```

end _arithmetic
...
(make C equal to 7.3)
start _arithmetic
C A plus B
end _arithmetic
...
(make D equal to 14.6)
start _arithmetic
D A plus B multiply 2.
end _arithmetic

```

Expressions will be evaluated from left to right. Words from define blocks will *not* be recognized in arithmetic blocks.

#### Automatic counting: the counters

The words **counter\_a**, **counter\_b**, **counter\_c** and **counter\_d** are reserved words in the data part. If they are found, they will be substituted by their integer value. After its value is substituted, the counter will be incremented by 1. Initially the value for counters is 0. The example below shows a typical application.

```

start _define
left _edge geometry _line counter _a
end _define
start _define
right _edge geometry _line counter _a
end _define
...
left _edge 0. 0. 0. 10. 1.e-4
right _edge 2. 0. 2. 10. 1.e-4
...
bounda _dof 1 -left _edge -velx
bounda _time 1 0.
bounda _dof 2 -right _edge -velx
bounda _time 2 1.3
...

```

Notice that we automatically give the geometry lines a unique number in this way; the unique number is not really of interest in the remainder of the input file, so the application of a counter is convenient.

Finally, also the words **counter\_a\_apply**, **counter\_b\_apply**, **counter\_c\_apply** and

**counter\_d\_apply** are available. They will be substituted by the current value of the counters, without that the counters are incremented.

### Conditional blocks

Parts of the input file can be processed conditionally within **start\_if ... end\_if** blocks. This is illustrated below with an example:

Example:

```
start_define
do_complete_calculation true
end_define
...
start_if do_complete_calculation
...
end_if
...
```

The part in the **start\_if ... end\_if** block is only done if **do\_complete\_calculation** is set to **true**, like in the example. If **do\_complete\_calculation** is set to **false** that part will be skipped. You also can use **start\_if\_not ... end\_if\_not** blocks, so that actions are NOT taken if the defined variable is set to true.

### Control indices

All possible data items are defined in the following sections. It only makes sense to specify some of the data items before the calculation; the other data items are only meant to be printed after the calculation. The example below specifies a 1D temperature calculation.

```
echo -no
number_of_space_dimensions 1
condif_temperature
end_initia

node 1 0
node 2 1
node 3 2

element 1 -bar2 1 2
element 2 -bar2 2 3
```

```

bounda_dof 0 1 -temp
bounda_time 0 0.0 0. 1. 1. 100. 1.
bounda_dof 1 3 -temp
bounda_time 1 0.0 0.0 100.0 0.

group_type 0 -condif
group_condif_density 0 1.0
group_condif_capacity 0 0.1
group_condif_conductivity 0 0.1
group_condif_flow 0 0.

control_timestep 0 0.1 10.0
control_print 0 -time_current -node_dof
control_print_database 1 -separate_index
control_timestep 2 0.2 10.0
control_print 2 -time_current -node_dof

end_data

```

Note how the indices of control items like **control\_timestep** and **control\_print** are used to control the sequence of events. First, (*index=0*) time steps of size 0.1 are taken and for each time step results are printed. Then (*index=1*) the database is printed which can serve as a point of restart. Finally (*index=2*) time steps of size 0.2 are taken and for each time step results are printed.

#### Define blocks

You can define a word to represent a set of strings. For each word defined, you need to specify a **start\_define ... end\_define** block. Within the block, you first specify the word, and then you specify the set of strings. Later in the data part, you can use the defined words as the replacement of the set of strings.

Example:

```

start_define
velocity 1.34
end_define
start_define
left_edge geometry_line 1
end_define
...
left_edge 0. 0. 0. 10. 1.e-4
...
bounda_dof 1 -left_edge -velx
bounda_time 1 0. 0. 100. velocity

```

...

The words **plus**, **minus**, **multiply** and **divide** as used in arithmetic blocks are prohibited in define blocks.

#### Include files

You can use **include** *filename* in the data part, to request that the file with name *filename* is included. This is handy to include often used data parts, or include a mesh generated by a pre-processor, etc.

The included file itself is not allowed to have an **include** in the data part.

The included file should not contain comments ( ... ). The included file needs to be ended with an **end\_data**. On some MS windows computers two **end\_data** records are needed, so try that in case of trouble. On MS windows 32 bit computers include is not available.

#### Numbering of values in records

The numbering of values in records is illustrated by **node\_dof** records. Look at the following piece of input file

```
...
number_of_space_dimensions 2
materi_velocity
materi_stress
end_initia
...
node_dof 1 0.0 0.0 -1.0 0.0 0.0 -1.0 0.0 -1.0
node_dof 2 0.0 0.0 -1.0 0.0 0.0 -1.0 0.0 -1.0
...
end_data
```

Here **node\_dof** records 1 and 2 are initialized. The initial velocities are 0, and for the initial stresses we use  $\sigma_{xx} = -1$ ,  $\sigma_{yy} = -1$  and  $\sigma_{zz} = -1$ . The total list of dof's in the **node\_dof** record is **-velx**, **-vely**, **-sigxx**, **-sigxy**, **-sigxz**, **-sigyy**, **-sigyz** and **-sigzz**.

We refer to **-velx** as the 0'th value in the **node\_dof** record, **-vely** as the 1'th value, etc. So printing the history of the **-sigxx** stress of **node\_dof** record 1 is obtained by this:

...

```

control__timestep 10 ...
control__print__history 10 -node__dof 1 2
...
end__data

```

where the number 2 refers to the **-sigxx** stress. See also the definition of the **control\_\_print\_\_history** record for this. As an alternative, sometimes you can use names instead of numbers, for example here:

```

...
control__timestep 10 ...
control__print__history 10 -node__dof 1 -sigxx
...
end__data

```

### Ranges

Ranges are general input formats used for indices and data values. Possible ranges are illustrated by the following examples

```

-all
-ra 12 32 44 -ra
-ra -from 5 -to 16 -ra
-ra -from 5 -to 25 -step 2 -ra

```

The **-all** range is not available for indices.

The data values for a data item can be specified as a range if this is allowed for in the description of the data item. All words in the data part (or part of an index) need to be preceded with a 'tic' (-). In the example the **node\_\_dof** records 1 to 100 are initialized

```

node__dof -ra -from 1 -to 100 -ra 1. 0. 0.

```

### Types of dof's

Some of the dof's are principal dof's: these are **materi\_\_velocity**, **condif\_\_temperature**, **groundflow\_\_pressure**, **wave\_\_fscalar**. These are the dof's which are solved by the equilibrium equations (conservation laws).

The other dof's, like **materi\_stress** and so, follow from these principal dof's (strains follow from displacement derivatives, stresses follow from strains by material laws, etc.).

Furthermore, for all the dof's we have primary values, which are the dof's themselves, and derived dof's, which are the space and time derivatives of the primary dof's.

## 6 Input file, data part, data records

### 6.1 `area_element_group` *index geometry\_entity\_item geometry\_entity\_index element\_group*

This record is used to generate **element\_group** records. Each element, all of whose nodes are part of the *geometry\_item*, will get an **element\_group** record with value *element\_group*. Please realise that the geometry entity can be a two-dimensional area, a volume, etc.

This option comes handy whenever a part of the domain gets some specific element data. For example, this would be the case if different areas in the structure have different material properties like stiffness, etc.

Beware: any directly specified **element\_group** records will be overwritten. Attention: default this **area\_element\_group** will only evaluated at the very start of the calculation. By setting *switch* in **area\_element\_group\_time** to **-yes** however you can require that this record is evaluated at all times.

We show here two ways to get different element data in different regions: Both ways give elements with young 1.2 from x=0 to x=1, and elements with young 3.3 from x=1 to x=2.

First way:

```
..
node 1 0.
node 2 1.
node 3 2.
element 1 -bar2 1 2
element 2 -bar2 2 3
element_group 1 0
element_group 2 1
..
group_type 0 -materi
group_materi_elasti_young 0 1.2
group_type 1 -materi
group_materi_elasti_young 1 3.3
..
control_mesh_refine_globally 10 -h_refinement
..
```

Second way:

```

node 1 0.
node 2 1.
node 3 2.
element 1 -bar2 1 2
element 2 -bar2 2 3
..
group_type 0 -materi
group_materi_elasti_young 0 1.2
group_type 1 -materi
group_materi_elasti_young 1 3.3
..
geometry_line 1 0. 1. 1.e-4
geometry_line 2 1. 2. 1.e-4
area_element_group 1 -geometry_line 1 0
area_element_group 2 -geometry_line 2 1
..

```

See also `area_element_group_method`, `area_element_group_sequence_element_group` etc.

## 6.2 `area_element_group_element` *index name*

With `area_element_group_element` you select the name of the elements for which the `area_element_group` will be used; if this `area_element_group_element` is not specified then all elements will be used.

## 6.3 `area_element_group_interface` *index switch*

If *switch* is set to **-yes** the `area_element_group` record with the same index will also be used for interface elements. If *switch* is set to **-no** the `area_element_group` record with the same index will not be used for interface elements. Presently the *switch* can be only set to **-no**.

## 6.4 `area_element_group_method` *index method*

Set *method* to **-all** or **-any**. If *method* is set to **-all**, then the corresponding `area_element_group` is applied to elements for which all nodes are inside the specified geometry. If *method* is set to **-any**, then the corresponding `area_element_group` is applied to elements for which any of the nodes is inside the specified geometry. If *method* is set to **-any\_but\_not\_all**, then the corresponding `area_element_group` is applied to elements for which any but not all of the nodes are inside the specified geometry. If *method* is set to a positive integer

number then the corresponding **area\_element\_group** is applied to elements for which at least such amount of the nodes is inside the specified geometry. Default *method* is **-all**.

### 6.5 **area\_element\_group\_node** *index node\_0 node\_1 ... element\_group*

Similar to **area\_element\_group**. Now, however, directly the global node numbers are specified.

### 6.6 **area\_element\_group\_time** *index switch*

If *switch* is set to **-yes** the corresponding **area\_element\_group** is evaluated at all times (as opposed to only at the start of the calculation).

### 6.7 **area\_element\_group\_sequence** *index element\_0 element\_1 ...*

See **area\_element\_group\_sequence\_element\_group**.

### 6.8 **area\_element\_group\_sequence\_element** *index name*

See **area\_element\_group\_sequence\_element\_group**.

### 6.9 **area\_element\_group\_sequence\_element\_group** *index group\_0 group\_1 ...*

#### General description

This option works more or less the same as the **area\_element\_group** option. Read that description first.

With this option however, you can specify what the element group numbers of an area (geometry), or set of element numbers, will be in time. This allows for an easy modeling of change of material models.

This option works in combination with the **area\_element\_group\_sequence\_\*** records (with the same index).

See also **control\_mesh\_change\_element\_group**.

Selection of elements for which the element group changes over time

With **area\_element\_group\_sequence\_geometry** you select the area (geometry) for which the time sequence of group numbers should be used.

With **area\_element\_group\_sequence** you select the elements for which the time sequence of group numbers should be used.

You can use both **area\_element\_group\_sequence\_geometry** and **area\_element\_group\_sequence** to select a combination of elements in a geometry and directly specified element numbers. As a completely separate option do not use any of **area\_element\_group\_sequence\_geometry** and **area\_element\_group\_sequence** at all. Then at a time point *time<sub>i</sub>* the elements which have group number *group<sub>(i-1)</sub>* will get new group number *group<sub>i</sub>*. So the previous group number of elements is used to set the current group number of elements (and geometries are not used to change the group numbers).

With **area\_element\_group\_sequence\_element** you select the name of the elements for which the sequence of time versus group will be used; if this **area\_element\_group\_sequence\_element** is not specified then all elements will be used.

#### Specification of new element group numbers in time

With **area\_element\_group\_sequence\_time** and **area\_element\_group\_sequence\_element\_group** you select time points at which groups should become active; for example, group\_0 becomes active at time\_0 etc.

#### Remarks

Remark 1: If you want the stresses, strains, etc. to be reset to 0. when the element group changes, then use a **control\_reset\_geometry** record for that.

Remark 2: It is more convenient and clear to use the **start\_define end\_define** option to define the geometries.

#### Examples

Example:

```
area_element_group_sequence_geometry 0 -geometry_brick 1
area_element_group_sequence_element 0 -hex8
area_element_group_sequence_time 0 0. 2. 3.
area_element_group_sequence_element_group 0 1 5 4

group_type 1 ...
...
group_type 5 ...
...
group_type 4 ...
...
control_reset_geometry 10 -geometry_brick 1
```

...

In the selected geometry element group 1 will be used starting from time 0 for elements **-hex8**. Starting from time 2 element group 5 will be used, etc. Same example, now with defines however:

```
start_define
soil_empty_wall geometry_brick 1
end_define
...

area_element_group_sequence_geometry 0 -soil_empty_wall
area_element_group_sequence_element 0 -hex8
area_element_group_sequence_time 0 0. 2. 3.
area_element_group_sequence_element_group 0 1 5 4

group_type 1 ...
...
group_type 5 ...
...
group_type 4 ...
...
control_reset_geometry 10 -soil_empty_wall
...
```

Now an example of the separate option:

```
area_element_group_sequence_time 0 0. 2. 3.
area_element_group_sequence_element_group 0 1 5 4

element_group 77 1
element_group 78 1

group_type 1 ...
...
group_type 5 ...
...
group_type 4 ...
```

At time 0. elements 77 and 78 have group number 1. At time 2. the elements with group number 1 get group number 5. At time 3. the elements with group number 5 get group number 4.

### 6.10 **area\_element\_group\_sequence\_geometry** *index geometry\_entity\_item geometry\_entity\_index*

See **area\_element\_group\_sequence\_element\_group**.

### 6.11 **area\_element\_group\_sequence\_geometry\_method** *index method*

Set *method* to **-all** or **-any**. If *method* is set to **-all**, then the corresponding **area\_element\_group\_sequence\_geometry** is applied to elements for which all nodes are inside the specified geometry. If *method* is set to **-any**, then the corresponding **area\_element\_group\_sequence\_geometry** is applied to elements for which any of the nodes is inside the specified geometry. Default *method* is **-all**.

### 6.12 **area\_element\_group\_sequence\_interface** *index switch*

If *switch* is set to **-yes** the **area\_element\_group\_sequence\_\*** will be used for interface elements also. If *switch* is set to **-no** the **area\_element\_group\_sequence\_\*** will not be used for interface elements. Default *switch* is set to **-no**.

### 6.13 **area\_element\_group\_sequence\_time** *index time\_0 time\_1 ...*

See **area\_element\_group\_sequence\_element\_group**.

### 6.14 **area\_node\_dataitem** *index geometry\_entity\_item geometry\_entity\_index data\_item\_name*

This record is used to generate *data\_item\_name* records on all nodes located on the specified geometrical entity. The values for the *data\_item\_name* should be specified in the **area\_node\_dataitem\_double** record for real precision values, or in the **area\_node\_dataitem\_integer** record for integer values (or words).

### 6.15 **area\_node\_dataitem\_double** *index value\_0 value\_1 ...*

See **area\_node\_dataitem**.

### 6.16 **area\_node\_dataitem\_integer** *index value\_0 value\_1 ...*

See **area\_node\_dataitem**.

### 6.17 axisymmetric *switch*

If *switch* is set to **-yes**, the calculation becomes axis-symmetrical. If *switch* is set to **-no**, the calculation becomes not axis-symmetrical. In case a **group\_axisymmetric** is specified for some group, that overrules this **axisymmetric** record.

### 6.18 **bounda\_\_alternate** *index bounda\_\_index\_0 bounda\_\_index\_1 ...*

This option takes care that between successive iterations only one of the specified **bounda\_\_dof** is not used. For example if **bounda\_\_dof** records with index 10, 20 and 30 are present in the input file, and you use **bounda\_\_alternate 10 20 30** then in subsequent iterations the following index is not used: 10, 20, 30, 10, 20, 30, 10, ... etc.

This option comes handy to allow for very large calculations on a computer with limited memory. By putting alternating boundary conditions on velocities, pressures or temperatures the system of active equations to be solved in each iterations is only of a limited size. And then using enough iterations the solutions for all dof's can slowly converge to the actual coupled solution.

As example consider a large 3d calculation where displacements and hydraulic pressure heads need to be solved:

```
solver__matrix__symmetric -yes
...
bounda__alternate 10 20 30 40
bounda__dof 10 -all -velx
bounda__dof 20 -all -vely
bounda__dof 30 -all -velz
bounda__dof 40 -all -pres
...
control__timestep 100 ..
control__timestep__iterations 100 20
```

The above **bounda\_\_dof** records are additional to the normally present records, like fixing displacements at sides of the domain, boundary conditions on hydraulic pressure, etc. The **bounda\_\_alternate** record instructs tochnog to subsequently neglect the record 10, 20, 30, 40, 10, ..., etc. When a record is neglected the corresponding solution field can be solved. For example in the first iteration the solution field for the x-displacement can be solved, while the y-displacement and z-displacement and hydraulic pressure head are kept fixed. And thus the total system of equations is much smaller, approximately 4 times less dof's need to be solved by the pardiso solver, which in fact is the bottleneck in computer memory usage for very large calculations. Notice that we asked tochnog to use the symmetric equation

solver, since the pressures and displacements are not used simultaneously, so we don't have the disadvantage of a non-symmetric matrix with displacement and pressure contributions.

As another example we use a classical staggered solution for displacements and water pressures:

```
solver_matrix_symmetric -yes
...
bounda_alternate 10 20
bounda_dof 10 -all -velx -vely -velz
bounda_dof 20 -all -pres
...
control_timestep 100 ..
control_timestep_iterations 100 20
```

You should not specify **bounda\_time** records i.c.w. **bounda\_dof** records which are used in **bounda\_alternate**. The **bounda\_time** records will not be used.

## 6.19 **bounda\_baseline\_correction** *time\_start time\_end*

If this record is specified baseline correction is performed after one of:

- reading SMC files with uncorrected accelerations in **bounda\_dof** i.c.w. **bounda\_time\_smc**.
- direct specification of acceleration in **bounda\_dof** i.c.w. **bounda\_time**.

Such baseline correction is needed to suppress artificial drift in velocity signals following from the acceleration signal.

The correction actually is done by adding a parabolic acceleration signal to the specified accelerations, thus giving a corrected acceleration in time. The parabolic (second order) signal contains three constant coefficients. These are determined by demanding that the corrected acceleration signal leads to a minimal sum of squared velocities over the considered time interval.

This correction is done over the time interval from *time\_start* up to *time\_end*. Typically *time\_start* *time\_end* are the start time and the end time of the time interval in which you apply base excitation. You need to specify these times in units that you actually use in your Tochnog calculation (so not in the units of the SMC file).

If this **bounda\_baseline\_correction** is not specified the data will be used directly without a correction.

See also **bounda\_baseline\_correction\_parameters**.

## 6.20 **bounda\_\_baseline\_\_correction\_\_parameters** *index ...*

The parameters for the parabolic baseline correction are written in this record. In future calculations you can use the parameters yourself by setting this record in the input file; then the parameters will not be determined again by the baseline correction algorithm; the parameters in the specified record will be used instead.

## 6.21 **bounda\_\_constant** *index switch*

This record can be used i.s.o. the **bounda\_\_time** record. If *switch* is set to **-yes** the prescribed dof's kept constant. This is only available for velocities, pressures and temperatures. This is not available for time derivatives **ttemp**, **tpres** and **ttotal\_\_pres**.

## 6.22 **bounda\_\_dof** *index node\_\_range dof\_0 dof\_1 ...*

States which dof's in which nodes get prescribed values by adjustment of the **node\_\_dof** records. The item *node\_\_range* represents a range of node numbers. In stead of a node range also, by example, **-geometry\_\_line 1** can be used, indicating that the nodes on line 1 get the prescribed boundary values. The items *dof\_0* etc. are one of the primary dof's listed at **dof\_\_label**.

For a specific *index*, only one of **bounda\_\_force** or **bounda\_\_dof** can be specified (thus either Neumann conditions or Dirichlet conditions).

Example for discrete node forces in y-direction on the nodes on a line:

```
bounda__dof 0 -geometry__line 1 -vely  
bounda__time 0 0. 0. 1. 1. 100. 1.
```

Normally you only should specify boundary conditions on principal dof's (like velocity, temperature, etc.) and not on strain, stresses, etc.!

Specially for velocity (displacement) dof's, you can prescribe that nodes should not move in a direction normal to a plane. For this, specify **-veln** for *dof\_0* to indicate that the normal velocity to a plane is 0. The normal direction should be given with **bounda\_\_normal**; if however a geometrical entity is used to specify the nodes, you do not necessarily need to specify the **bounda\_\_normal**, thus the normal from the geometrical entity is then used instead. The **bounda\_\_time** record should not be specified (it is irrelevant). Internally in Tochnog a multi-point-constraint will be generated to accomplish this condition of zero velocity in normal direction.

Specially for velocity (displacement) dof's, you can prescribe a rotation around either the x-axis, y-axis or z-axis. In 1D you cannot use this record. In 2D you can only specify a

rotation around the z-axis. In 3D you can specify each of the three axis. Example of an x-axis rotation of node 12 with angular velocity of 0.33 [degrees per unit time]:

```
bounda_dof 0 12 -rotation_x_axis
bounda_time 0 0.33
```

For the rotation 0.33 the rotation vector points in the positive x-axis direction.

Specially for the groundflow phreatic head  $h$ , you can prescribe the physical pore pressure **-total\_pressure** and Tochnog will automatically calculate the corresponding hydraulic pressure head  $h$ . Also specially for the groundflow phreatic head  $h$ , you can prescribe the time rate of the physical pore pressure **-ttotal\_pressure** and Tochnog will automatically calculate the corresponding hydraulic pressure head  $h$ . Also specially for the groundflow phreatic head  $h$ , you can prescribe the time rate of the hydraulic pressure head **-tpres**. Specially for the temperature you can prescribe the time rate of the temperature **-ttemp**.

As a special option you can specify also, for example, **-element\_group 1** in stead of a node range. Then nodes of elements which have **element\_group** set to 1 will get the prescribed boundary values.

As a special option you can specify also, for example, **-element\_geometry 1** in stead of a node range. Then nodes of elements which have **element\_geometry** set to 1 will get the prescribed boundary values.

As a special option you can specify also, for example, **-geometry\_set 1** in stead of a node range. Then nodes of elements which have any of the elements belonging to **geometry\_set 1** will get the prescribed boundary values.

Notice: if several **bounda\_dof** records act on a node, only the record with the highest index will be used.

See also: **bounda\_time**, **bounda\_sine**, **bounda\_constant**, **bounda\_dof\_radial**, **bounda\_dof\_cylindrical**, **force\_edge** and **force\_volume**.

### 6.23 **bounda\_dof\_cylindrical** *index x\_first y\_first z\_first x\_second y\_second z\_second*

Specially for velocity (displacement) dof's, you can prescribe velocities cylindrical to a line specified with the point  $x\_first$ ,  $y\_first$ ,  $z\_first$  and  $x\_second$ ,  $y\_second$ ,  $z\_second$ ; in 1D only  $x$  values should be specified, and in 2D only  $x$ ,  $y$  values should be specified. Example:

```
bounda_dof 10 -ra ... -ra -velx -vely -velz
```

```

bounda_dof_cylindrical 10 1.23 3.43 5.12 1.23 3.43 15.12
bounda_time 10 0. 0. 1. 1. 100. 1.

```

The velocity increases linearly in size away from the specified line (at unit distance away from the line the velocity has size 1; you can scale it by the **bounda\_time** record).

#### 6.24 **bounda\_dof\_radial** *index x y z*

Specially for velocity (displacement) dof's, you can prescribe velocities radial to a specified point  $x, y, z$ ; in 1D only  $x$  should be specified, and in 2D only  $x, y$  should be specified. Example:

```

bounda_dof 10 -ra -ldots -ra -velx -vely -velz
bounda_dof_radial 10 1.23 3.43 5.12
bounda_time 10 0. 0. 1. 1. 100. 1.

```

A radial velocity is prescribed on nodes in a specified range, relative to point 1.23, 3.43, 5.12 and with the time table given by **bounda\_time**. The velocity increases linearly in size away from the specified point  $x, y, z$  (at unit distance away from the specified point  $x, y, z$  the velocity has size 1; you can scale it by the **bounda\_time** record).

#### 6.25 **bounda\_factor** *index $a_0 a_1 \dots a_n$*

This data item defines a polynomial in space. This polynomial gives a factor which is used as a multiplication factor for **bounda\_time** records (with the same index). In this way, you can obtain coordinate dependent boundary conditions.

In 1D the polynomial is  $a_0 + a_1x$  (specify 2 values). In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values). In 3D the polynomial is  $a_0 + a_1x + a_2y + a_3z$  (specify 4 values).

#### 6.26 **bounda\_factor\_parabolic\_x** *index $a_0 a_1 a_2$*

This data item defines a quadratic polynomial in x-direction.

The polynomial is  $a_0 + a_1x + a_2x^2$  (specify 3 values).

### 6.27 **bounda\_force** *index node\_range dof\_0 dof\_1 ...*

States which ones from the list of dof's in which nodes get prescribed nodal forces. The item *node\_range* represents a range of node numbers. In stead of a node range also, for example, **-geometry\_line 1** can be used, indicating that the nodes on line 1 get the prescribed nodal forces. The items *dof\_0* etc. can be one of the items listed at **dof\_label**. However, neither **-dis** and **-scal** can be used.

For a specific *index*, only one of **bounda\_force** and **bounda\_dof** can be specified; thus, either Neumann conditions or Dirichlet conditions can be applied to a particular node, but nor both.

Attention: with this option you get the same nodal force on all the specified nodes. If you want to apply a distributed force on a edge, however, you should use **force\_edge**. That option gives forces consistent with the displacement field, so not necessarily the same for all nodes. For example the nodes on the side of linear elements on a edge get only half the force.

As a special option you can specify also, for example, **element\_geometry 1** in stead of a node range. Then nodes of elements which have **element\_group** set to 1 will get the prescribed nodal forces.

Notice: if several **bounda\_force** records act on a node, the imposed forces are summed.

See also: **bounda\_time**, **bounda\_sine** and **force\_edge**.

### 6.28 **bounda\_found** *index found*

This record is meant for printing only. A value of **-yes** indicates that the corresponding **bounda\_\*** records are indeed used at some nodes. A value of **-no** indicates that the corresponding **bounda\_\*** records are not used at all at some nodes.

### 6.29 **bounda\_geometry\_method** *index node\_type*

If boundary conditions are imposed on a geometry, you can set with this record which node type should be used. If *node\_type* is set to **-node\_start\_refined** the values of **-node\_start\_refined** are used to determine if nodes are located on the geometry. If *node\_type* is set to **-node** the values of **-node** are used to determine if nodes are located on the geometry. If *node\_type* is set to **-plus\_displacement** the values of **-node** plus nodal displacements are used to determine if nodes are located on the geometry.

### 6.30 **bounda\_normal** *index normal\_x normal\_y normal\_z*

This record specifies the components of a normal vector to a plane on which nodes should slide (the nodes are not allowed to move normal to the plane). In 3D you need to specify all of *normal\_x normal\_y normal\_z*. In 2D you need to specify only *normal\_x normal\_y*. In 1D you need to specify only *normal\_x*.

See also **bounda\_dof**.

### 6.31 **bounda\_print\_mesh\_dof** *dof\_0 dof\_1 ...*

See **print\_mesh\_dof**.

### 6.32 **bounda\_print\_mesh\_dof\_geometry** *geometry\_item\_name geometry\_item\_index*

See **print\_mesh\_dof**.

### 6.33 **bounda\_print\_mesh\_dof\_values** *value\_dof\_0 value\_dof\_1 ...*

See **print\_mesh\_dof**.

### 6.34 **bounda\_sine** *index start\_time end\_time freq\_0 amp\_0 freq\_1 amp\_1 ...*

The **bounda\_dof** or **bounda\_force** record with the same *index* is imposed with the sum of the sine functions; the first sine function has frequency *freq\_0* and amplitude *amp\_0*, the second sine function has frequency *freq\_1* and amplitude *amp\_1*, etc.. More general behavior in time can be imposed by using **bounda\_time** records. For a specific *index* only one of **bounda\_time** and **bounda\_sine** can be specified.

As a typical application the response due to the excitation with a frequency spectrum can be analyzed. Just print the relevant response by **control\_print\_history** and extract the frequency spectrum of that response signal.

The sine loads will be only imposed after *start\_time*, and will not be imposed anymore after *end\_time*. The sine functions start at time *start\_time* (then they have value 0).

As a special option setting a frequency to 0 enforces tochnog to use a constant static value of the specified amplitude.

### 6.35 **bounda\_\_time** *index time load time load ...*

This record specifies a multi linear time-load diagram for the **bounda\_\_dof** or **bounda\_\_force** record with the same *index*. Between two time points in the diagram, the load is interpolated linearly (ramp function between the two points).

At all times that an *dof* is not prescribed in such way, it is free and determined with the governing differential equations. For a specific *index* only one of **bounda\_\_time**, **bounda\_\_sine** and **bounda\_\_time\_\_user** can be specified.

As a special option, you can specify only one value in the **bounda\_\_time** record if the load is constant over time (so not time-load sets but directly the constant load value).

As a further special option, you can specify no **bounda\_\_time** and no **bounda\_\_sine** at all; then a 0 value is assumed.

### 6.36 **bounda\_\_time\_\_factor** *index factor*

With this record you can specify an multiplication factor to be used for loads specified by **bounda\_\_time**. This option comes handy when you import a time-load table from some external data source, which uses some other definition of the load as you do in the tochnog input file. For example, if you specify accelerations in metric units but the external source specifies the accelerations as part of the gravity acceleration, you can convert the load in the time-load table with this factor.

Default, if **bounda\_\_time\_\_factor** is not specified, the factor is set to 1.

### 6.37 **bounda\_\_time\_\_offset** *index time\_\_offset*

With this record you can specify an offset to be used for times specified by **bounda\_\_time**. The actual times will become time offset added to the specified times in **bounda\_\_time**. This option comes handy when you import a time-load table from some external data source, but would like to apply the table at a different moment in time in the calculation. You need to specify *time\_\_offset* in the units that you actually use in your calculation.

### 6.38 **bounda\_\_time\_\_increment** *index time\_\_increment*

With this record you can specify that the data as specified in **bounda\_\_time** is only the load data, so not time points anymore. The time points are automatically calculated from a fixed time increments (and optionally an initial offset as specified in **bounda\_\_time\_\_offset**). For example:

...

```

bounda_dof 10 -geometry_line -accx
bounda_time 10 0.2 0.78 1.33 ... (acceleration data only)
bounda_time_offset 10 1. (the accelerations start at time 1)
bounda_time_increment 10 0.05 (the increments in time are 0.05)
(thus the acceleration is spcified at times 1.0, 1.05., 1.10, 1.15, etc.)
...

```

In this example the acceleration is 0.2 at time 1, it is 0.78 at time 1.05, etc.

### 6.39 **bounda\_time\_units** *factor\_time factor\_length*

The specified times and data in **bounda\_time** may have other units then you actually apply in your calculation. With *factor\_time* you correct the time in **bounda\_time** to get times consistent with your calculation. With *factor\_length* you can correct the data in **bounda\_time** to get data consistent with your calculation. For example, if **bounda\_time** contains [sec] and [cm] and if your actual calculation uses [hour] and [m] then set *factor\_time* to 3600. and set *factor\_length* to 100. This option is presently only available for prescribed accelerations.

### 6.40 **bounda\_time\_until\_data** *data\_item\_name data\_item\_index date\_item\_number*

With this option you can set how much the **bounda\_time** record with the same index should be applied. Tochnog will look at the value of *data\_item\_name data\_item\_index date\_item\_number*. If that value is lower than *start* Tochnog will start to reduce the applied value in **bounda\_time**. This reduced value will become 0 at the moment that the value of *data\_item\_name data\_item\_index date\_item\_number* reaches *wanted*.

A typical application is to slowly reduce prescribed velocities/displacements on a structure so that a minimum force response of the structure is obtained. This would look like:

```

...
bounda_dof 210 ... -vely ( apply velocity on structure)
bounda_time 210 ...
bounda_time_until_data 210 -post_node_result 10 -vely ( monitor
structure force response )
( reduce prescribed displacement when force response
is below 30 percent of initial value )
( the reduced velocity will become zero when the force response
reaches 10 percent of initial value )
bounda_time_until_value_minimum 210 0.1 0.3
...

```

#### 6.41 `bounda_time_until_value_minimum` *wanted start*

See `bounda_time_until_data`.

#### 6.42 `bounda_time_smc` *index switch*

If *switch* is set to **-yes** the SMC file *index.smc* will be read. Such Strong Motion CD file (SMC file) contains base acceleration time data. This option can be used to read SMC files strictly following the definition from <http://nsmp.wr.usgs.gov/smcfmt.html>. A typical input example for a SMC file looks like:

```
...
materi_velocity
materi_stress
...
end_initia
...
bounda_baseline_correction 1. 1.1 (correct acceleration for time 1
to 1.1
...
bounda_dof 10 -geometry_line -accx
bounda_time_smc 10 -yes
bounda_time_smc_offset 10 1. (the base excitation starts at time 1)
bounda_time_smc_units 10 3600. 100. (we use hours and meters)
...
control_timestep 10 1.e-2 1. (gravity from time 0 to 1)
...
control_timestep 20 1.e-6 0.1 (base excitation from time 1 to 1.1)
...
```

In case the SMC file does not strictly follow the definition from <http://nsmp.wr.usgs.gov/smcfmt.html>, the option `bounda_time_smc` cannot be used. In such case you can use the actual data lines in a `bounda_time` record as follows:

```
...
materi_velocity
materi_stress
...
end_initia
...
bounda_baseline_correction 1. 1.1 (correct acceleration for time 1
to 1.1
```

```

...
bounda_dof 10 -geometry_line -accx
include acceleration.dat (include file containing bounda_time 10 ..., the
dots ... represent acceleration data)
bounda_time_offset 10 1. (the base excitation starts at time 1)
bounda_time_units 10 3600. 100. (we use hours and meters)
...
control_timestep 10 1.e-2 1. (gravity from time 0 to 1)
...
control_timestep 20 1.e-6 0.1 (base excitation from time 1 to 1.1)
...

```

Be sure that you take sufficient small time increments while performing the base acceleration steps. See also <http://nsmp.wr.usgs.gov/>.

#### 6.43 **bounda\_time\_smc\_offset** *index time\_offset*

The times of the SMC file are incremented with *time\_offset*, such that you can use the acceleration data starting from any time point in a calculation. If this record is not specified then *time\_offset* is set to 0.

#### 6.44 **bounda\_time\_smc\_units** *factor\_time factor\_length*

The SMC files have units [cm] for length and [sec] for time. Your input file may have other units however. With *factor\_time* you correct the time read from the SMC file to get times consistent with your input file. With *factor\_length* you can correct the data (acceleration, velocity or displacement) read from the SMC file to get data consistent with your input file. For example, if you use [hour] and [m] in your calculation then set *factor\_time* to 3600. and set *factor\_length* to 100.

#### 6.45 **bounda\_time\_user** *index switch*

If *switch* is set to **-yes** a user supplied routine for the time-load diagram will be used.

See also the file **user.cpp** in the distribution.

#### 6.46 **bounda\_water** *index switch*

If *switch* is set to **-yes**, and you specify the pore pressure **-total\_pressure** as dof, the pore pressure is actually determined from the height of the water column between the node and

the phreatic level. In fact the pore pressure is set to  $\text{density\_water} \cdot g \cdot \Delta z$  where  $g$  is the gravitational acceleration, and  $\Delta z$  is the distance to the phreatic level.

The water density is given by **groundflow \_density**. The gravity acceleration is given by the vertical component of **force \_gravity**. The water height is relative to the water height is given by **groundflow \_phreatic \_level**.

In this case the record **bounda \_time** does not contain the actual value of the pore pressure, but instead it only contains a multiplication factor for the static water pressure as calculated above.

This **bounda \_water** is convenient when the phreatic level is located above the FE mesh. Then this option allows you to impose a pressure boundary condition for the nodes in the FE mesh at the top boundary of the mesh, automatically using a specified phreatic level record.

#### 6.47 **change \_dataitem** *index data \_item \_name data \_item \_index data \_item \_number \_0 data \_item \_number \_1 ... operat*

With this record you can specify a data item which should be changed over time. The time table should be given in the **change \_dataitem \_time** table as time-value sets; at least two sets should be specified.

The *operat* determines how the time-value sets are used. If *operat* is set to **-use**, then the value of the time-value sets is directly used. If *operat* is set to **-add**, then the value of the time-value sets is interpreted as a rate of change, so that the value is multiplied with the time step and then added to the old value.

Notice that you can change multiple numbers at once.

As a typical example you can use this to prescribe the displacement of a contact geometry over time. Below the y-coordinates of a geometry line which is used in the contact algorithm is changed over time:

```
contact _target _geometry 0 -geometry _line 1
...

geometry _line 1 0. 10. 2. 10.
...

change _dataitem 0 -geometry _line 1 1 -use
change _dataitem _time 0 0. 10. 100. 0.
change _dataitem 1 -geometry _line 1 3 -use
change _dataitem _time 1 0. 10. 100. 0.
...
```

The specified values are evaluated at the start of each timestep.

#### 6.48 **change\_dataitem\_geometry** *index geometry\_entity\_name geometry\_entity\_index*

For element group data **group\_\*** you can restrict the application for the **change\_dataitem** to only those elements which are part of the geometry specified by *geometry\_entity\_name* *geometry\_entity\_index*.

#### 6.49 **change\_dataitem\_time** *index time value ...*

See **change\_dataitem** and **change\_dataitem\_time\_user**.

#### 6.50 **change\_dataitem\_time\_discrete** *index switch*

If *switch* is set to **-yes** then the changes applied by the **change\_dataitem** and **change\_dataitem\_time** records (with the same index), will be applied at the discrete time points given in **change\_dataitem\_time**. Between those time points, no interpolation is used.

More precise, the change of the data item will be applied directly after the time point has passed.

If you don't specify this **change\_dataitem\_time\_discrete** record then interpolation is used.

#### 6.51 **change\_dataitem\_time\_method** *index method*

With this record you can require that the cosinus, sinus or tangent of a data value will be changed (in stead of the data value directly itself). The *method* can be set to either **-cosinus**, **-sinus** or **-tangent**. This is typically convenient for geotechnical safety factor calculations where you want that for a mohr coulomb law the cohesion and tangent of the friction angle are decreased at the same ratio in time.

Example:

```
...  
group_materi_plasti_mohr_coul_direct 10 ...  
...
```

```

(tangent of friction angle reduction)
change __dataitem 10 -group __materi __plasti __mohr __coul __direct 10 0
-use
change __dataitem __time 10 ... (specify tangent values here)
change __dataitem __time __method 10 -tangent
...
(cohesion reduction)
change __dataitem 20 -group __materi __plasti __mohr __coul __direct 10 1
-use
change __dataitem __time 20 ...
...

```

As an extra remark on such 'phi - c' reduction: if you want to calculate the safety factor of the initial geometry you should not use the **mesh -follow \_\_material ...** option, since with that the soil would be able to deform to new stable configurations.

## 6.52 change \_\_dataitem \_\_time \_\_user *index switch*

If *switch* is set to **-yes** a user supplied subroutine is used instead of the **change \_\_dataitem \_\_time** table.

See also the **user.cpp** routine included in the distribution.

## 6.53 check \_\_data *switch*

If *switch* is set to **-yes** the in-core database is checked at some moments during the calculation. You can try this option in case you experience unexpected behavior.

## 6.54 check \_\_error *switch*

Tochnog will does some error checking which you can suppress by setting *switch* to **-no**.

## 6.55 check \_\_element \_\_node *index switch*

Tochnog will check that elements do not have duplicate nodes. If you want to have duplicate nodes on purpose however, you can set *switch* to **-no** so that this checking is suppressed.

### 6.56 **check\_element\_shape** *index factor*

Isoparametric elements are mapped from the isoparametric space to the real coordinate space with shape functions. The determinant of the Jacobian of the mapping will have the same value in each integration point if elements are not distorted by the mapping. Thus the relative difference  $\frac{det_{ip}-det_{average}}{det_{average}}$  in each integration point of an element measures the distortion.

Tochnog determines the average of the relative difference for all the integration points in an element.

If this average is larger then *factor* a warning message will be printed. Furthermore, if **check\_element\_shape** is specified the average will be stored in a record **element\_shape** in the database dbs file; the average will be plotted in the GID post-processing files so that you can visually inspect where the elements are most distorted.

Perfectly non-distorted isoparametric elements have average 0.

Severely distorted elements have a high average, e.g. larger than 0.25.

### 6.57 **check\_memory** *index switch*

If *switch* is set to **-yes**, Tochnog checks memory usage of the calculation. If *switch* is set to **-no**, Tochnog does not check memory usage of the calculation.

When checking memory usage Tochnog checks that the calculation fits in the computer RAM memory. Furthermore, on 32 bit systems Tochnog checks that array sizes do not exceed 2Gb.

Default, if **check\_memory** is not specified, the *switch* is set to **-no**.

### 6.58 **check\_memory\_usage** *index switch*

If *switch* is set to **-yes** Tochnog keeps record of the highest memory used by the calculation. It will put that highest usage, expressed in GB, in the record **check\_memory\_usage\_result**. This option comes convenient to keep an eye on the memory usage of a calculation, in case you are reaching the limit on your computer. You need to prevent that memory usage exceeds the amount of RAM memory, since swapping to disk is extremely slow.

This option is only available on 64 bit linux. Default, if **check\_memory\_usage** is not specified, then *switch* is set to **-yes**.

### 6.59 **check\_\_memory\_\_usage\_\_result** *index memory*

See **check\_\_memory\_\_usage**.

### 6.60 **check\_\_nan** *switch*

If *switch* is set to **-yes** some internal result (stresses, etc.) are check for being NAN. NAN represents Not A Number , meaning that the computer cannot represent the result by a number. This means that something is wrong: the solution may have diverged, or you may have a programming error in a user supplied routine, or etc.

### 6.61 **check\_\_solver** *eps*

If this record is set the solver checks if diagonal terms are smaller than *eps*. That normally indicates some problem in your input file if *eps* is very small.

### 6.62 **check\_\_target** *switch*

If you set switch to **-no**, any **target\_\_\*** records will be neglected. THis allows to run the input file without getting error messages in the log file, for example when testing variations of the input file.

### 6.63 **check\_\_used** *switch*

If *switch* is set to **-yes**, Tochnog will check if input data is really used. It will give a message if some input data is not used. In fact, this option will only check if any index of a certain data item is used; thus if any index of a certain data item in the input file has been used in the calculation, all indices of that data item are considered to be used, and no message will be given.

This option comes handy when looking for errors in input files.

Default, when **check\_\_used** is not specified, *switch* is set to **-no**.

### 6.64 **check\_\_warning** *switch*

Tochnog will does some warning checking which you can suppress by setting *switch* to **-no**.

### 6.65 **condif\_convection\_edge\_normal** *index* $\alpha_c$ $T_r$

Convection coefficient and convection environmental temperature. Also the record **condif\_convection\_edge\_normal\_geometry** should be specified.

Attention: this option is only available for linear and quadratic isoparametric elements.

### 6.66 **condif\_convection\_edge\_normal\_element** *index* *element\_0 element\_1 ...*

Selects the elements for which the **condif\_convection\_edge\_normal** record with the same *index* should be applied.

### 6.67 **condif\_convection\_edge\_normal\_element\_group** *index* *element\_group\_0 element\_group\_1 ...*

Selects the element groups for which the **condif\_convection\_edge\_normal** record with the same *index* should be applied.

### 6.68 **condif\_convection\_edge\_normal\_element\_node** *index* *element\_node\_0 node\_1 ...*

Selects the element and local node numbers for which the **condif\_convection\_edge\_normal** record with the same *index* should be applied.

### 6.69 **condif\_convection\_edge\_normal\_element\_side** *index* *element\_0 element\_1 ... side*

Selects the elements and local side number for which the **condif\_convection\_edge\_normal** record with the same *index* should be applied.

### 6.70 **condif\_convection\_edge\_normal\_geometry** *index* *geometry\_entity\_name geometry\_entity\_index*

Selects the area for which the **condif\_convection\_edge\_normal** record with the same *index* should be applied.

Instead of a number of nodes also, for example, **-geometry\_line 1** can be used in 2D, indicating that the nodes on line 1 start to convect. The total edge of an element must be inside

the geometry for the force to become active. For 2D elements the border lines are edges. For 3D elements the border surfaces are edges. See also: **condif\_convection\_edge\_normal**.

#### 6.71 **condif\_convection\_edge\_normal\_node** *index node\_0 node\_1 ...*

Selects the nodes for which the **condif\_convection\_edge\_normal** record with the same *index* should be applied. The *node\_0* etc. specifies the global node numbers.

#### 6.72 **condif\_heat\_edge\_normal** *index heat*

Distributed prescribed heat flux normal normal to the edge of a element. This distributed heat is translated into equivalent nodal heat on the edges of elements. Also the record **condif\_heat\_edge\_normal\_geometry** should be specified, and optionally the record **condif\_heat\_edge\_normal\_time** can be specified.

Attention: this option is only available for linear and quadratic isoparametric elements.

Attention: if this option is used INSIDE a FE mesh, then the elements on each side will get the distributed heat. So the total heat flux will normally become zero since the normals of the elements at the side of the geometry are opposite.

#### 6.73 **condif\_heat\_edge\_normal\_element** *index element\_0 element\_1 ...*

Restricts the elements to which the **condif\_heat\_edge\_normal** record with the same *index* should be applied.

**6.74** `condif_heat_edge_normal_element_group` *index element\_group\_0  
element\_group\_1 ...*

Restricts the element groups to which the `condif_heat_edge_normal` record with the same *index* should be applied.

**6.75** `condif_heat_edge_normal_element_node` *index element node\_0  
node\_1 ...*

Selects the element and local node numbers for which the `condif_heat_edge_normal` record with the same *index* should be applied.

**6.76** `condif_heat_edge_normal_element_node_factor` *index factor\_0  
factor\_1 ...*

Nodal multiplication factors with which the `condif_heat_edge_normal` will be applied to the element of `condif_heat_edge_normal_element_node`. You need to specify a factor for each node on the side. Here *factor<sub>0</sub>* is the multiplication factor for the first node on the side, etc.

**6.77** `condif_heat_edge_normal_element_side` *index element\_0 el-  
ement\_1 ... side*

Selects the elements and local side number for which the `condif_heat_edge_normal` record with the same *index* should be applied.

**6.78** `condif_heat_edge_normal_factor` *index a<sub>0</sub> a<sub>1</sub> ... a<sub>n</sub>*

This data item defines a polynomial in space. This polynomial gives a factor which is used as a multiplication factor for `condif_heat_edge_normal` records (with the same index). In this way, you can obtain coordinate dependent heat fluxes.

In 1D the polynomial is  $a_0 + a_1x$  (specify 2 values). In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values). In 3D the polynomial is  $a_0 + a_1x + a_2y + a_3z$  (specify 4 values).

**6.79** **condif\_heat\_edge\_normal\_geometry** *index geometry\_entity\_name geometry\_entity\_index*

Selects the area for which the **condif\_heat\_edge\_normal** record with the same *index* should be applied. For example, **-geometry\_line 1** can be used in 2D, indicating that the nodes on line 1 get the distributed heat. The total edge of an element must be inside the geometry for the force to become active. For 2D elements the border lines are edges. For 3D elements the border surfaces are edges.

**6.80** **condif\_heat\_edge\_normal\_node** *index node\_0 node\_1 node\_2 ...*

Selects the nodes for which the **condif\_heat\_edge\_normal** record with the same *index* should be applied. The *node\_0* etc. specify global node numbers.

**6.81** **condif\_heat\_edge\_normal\_sine** *index start\_time end\_time freq\_0 amp\_0 freq\_1 amp\_1 ...*

Similar to **force\_edge\_sine**, now for heat flux however.

**6.82** **condif\_heat\_edge\_normal\_time** *index time load time load ...*

This record specifies a diagram which contains the factors with which the **condif\_heat\_edge\_normal** record with the same *index* is applied. Linear interpolation is used to extend the *time load* values to the intervals between these pairs. Outside the specified time range a factor 0 is used.

If this record is not specified, the heat flux is applied at all times with a factor 1.

**6.83** **condif\_heat\_volume** *index heat*

Distributed volume heat source. Here *heat* is the distributed heat source value.

See also **condif\_heat\_volume\_factor**, **condif\_heat\_volume\_geometry**, and **condif\_heat\_volume\_time**.

**6.84** **condif\_heat\_volume\_element** *index element\_0 element\_1 ...*

Specifies the elements for which the **condif\_heat\_volume** record with the same *index* should be applied.

### 6.85 **condif\_heat\_volume\_element\_group** *index element\_group*

Specifies the element group for which the **condif\_heat\_volume** record with the same *index* should be applied.

### 6.86 **condif\_heat\_volume\_factor** *index a<sub>0</sub> a<sub>1</sub> ... a<sub>n</sub>*

This polynomial gives a factor which is used as a multiplication factor for **condif\_heat\_volume** records (with the same index). In this way, you can obtain coordinate dependent forces.

In 1D the polynomial is  $a_0 + a_1x$  (specify 2 values). In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values). In 3D the polynomial is  $a_0 + a_1x + a_2y + a_3z$  (specify 4 values).

### 6.87 **condif\_heat\_volume\_geometry** *index geometry\_name geometry\_index*

Specifies the geometry for which the **condif\_heat\_volume** record with the same *index* should be applied.

### 6.88 **condif\_heat\_volume\_sine** *index start\_time end\_time freq\_0 amp\_0 freq\_1 amp\_1 ...*

Similar to **force\_edge\_sine**, now for volume heat source however.

### 6.89 **condif\_heat\_volume\_time** *index time load time load ...*

This record specifies a multi-linear diagram which contains the factors with which the **condif\_heat\_volume** record with the same index is applied.

If this record is not specified, the heat source is applied at all times with a factor 1.

### 6.90 **condif\_heat\_volume\_user** *index switch*

Set *switch* to **-yes** if you want to call the user supplied routine for heat.

### 6.91 **condif\_heat\_volume\_user\_parameters** *index ...*

Specify the parameters for the user supplied routine for heat.

### 6.92 **condif\_radiation\_edge\_normal** *index* $\alpha_r$ $T_r$

Radiation coefficient and radiation environmental temperature. Also the record **condif\_radiation\_edge\_normal** should be specified.

Attention: this option is only available for linear and quadratic isoparametric elements.

### 6.93 **condif\_radiation\_edge\_normal\_element** *index element\_0 element\_1 ...*

Selects the elements for which the **condif\_radiation\_normal\_edge** record with the same *index* should be applied.

### 6.94 **condif\_radiation\_edge\_normal\_element\_node** *index element node\_0 node\_1 ...*

Selects the element and local node numbers for which the **condif\_radiation\_edge\_normal** record with the same *index* should be applied.

### 6.95 **condif\_radiation\_edge\_normal\_element\_group** *index element\_group\_0 element\_group\_1 ...*

Selects the element groups for which the **condif\_radiation\_normal\_edge** record with the same *index* should be applied.

### 6.96 **condif\_radiation\_edge\_normal\_element\_side** *index element\_0 element\_1 ... side*

Selects the elements and side number for which the **condif\_radiation\_edge\_normal** record with the same *index* should be applied.

### 6.97 **condif\_radiation\_edge\_normal\_geometry** *index geometry\_entity\_name geometry\_entity\_index*

Selects the area for which the **condif\_radiation\_edge\_normal** record with the same *index* should be applied.

In stead of a number of nodes also, for example, **-geometry\_line 1** can be used in 2D, indicating that the nodes on line 1 radiate heat. The total edge of an element must be inside

the geometry for the force to become active. For 2D elements the border lines are edges. For 3D elements the border surfaces are edges. See also: **condif\_radiation\_edge\_normal**.

#### 6.98 **condif\_radiation\_edge\_normal\_node** *index node\_0 node\_1 ...*

Selects the nodes for which the **condif\_radiation\_edge\_normal** record with the same *index* should be applied. This is only available for linear elements. The *node\_0* etc. specifies the global node numbers.

#### 6.99 **contact\_apply** *index switch*

If *switch* is set to **-yes**, the contact algorithm is used. If *switch* is set to **-no**, the contact algorithm is not used. This is done for all timestep records.

See also **control\_contact\_apply**.

#### 6.100 **contact\_heat\_generation** *factor*

This *factor* specifies how much of the frictional energy is transformed into heat (this only makes sense if *friction* in **contact\_plasti\_friction** is not zero, and if **condif\_temperature** is initialized). The *factor* should be between 0 and 1. See also **contact\_target\_geometry**.

#### 6.101 **contact\_penalty\_pressure** *pressure\_penalty*

The *pressure\_penalty* should be given some high value if the pressure is freely linked at the surfaces of contactor and target. See also **contact\_target\_geometry**.

### 6.102 **contact\_penalty\_temperature** *temperature\_penalty*

The *temperature\_penalty* should be given some high value if free heat exchange between contactor and target is possible. See also **contact\_target\_geometry**.

### 6.103 **contact\_penalty\_velocity** *velocity\_penalty*

The **velocity\_penalty** essentially puts a spring between the contactor and the target if penetration occurs. Iterations (see **control\_timestep\_iterations**) are needed; more iterations are needed if the penalty factor is higher. See also **contact\_target\_geometry**.

### 6.104 **contact\_plasti\_friction** *friction*

See **contact\_target\_geometry**.

### 6.105 **contact\_target\_element\_group** *element\_group\_0 element\_group\_1* ...

This records defines the element groups for which the elements function as target in a contact analysis. It is advised to use different element groups for the contacting and target elements, so that the contact algorithm can distinguish between both. The target element group should consist of more than 1 layer of elements in contact direction (so only one layer of target elements is not allowed). The contactor should be smaller of size than the target.

See also **contact\_target\_geometry**.

### 6.106 **contact\_target\_geometry** *index geometry\_entity\_item geometry\_entity\_index*

Attention: the contact algorithm is experimental up to now, and may not work for all calculations.

This record specifies a contact geometry. Contacting nodes are forced to stay at the outward normal side of the contact geometry.

The allowed geometries and their material outward normals are listed below

- If a **geometry\_point** is used in 1D, the normal is in positive x-direction.
- If a **geometry\_line** is used in 2D, the normal is the outer product of 3-direction and the line direction (from point 0 to point 1).
- If a **geometry\_circle** is used in 2D, the normal is the outward direction at the circle.

- If a **geometry\_\_circle** is used in 3D, the normal is the outward direction on the circle surface.
- If a **geometry\_\_ellipse** is used in 2D, the normal is the outward direction at the ellipse.
- If a **geometry\_\_sphere** is used in 3D, the normal is the outward direction at the sphere.
- If a **geometry\_\_polynomial** is used in 2D, the normal is in positive y-direction.
- If a **geometry\_\_polynomial** is used in 3D, the normal is in positive z-direction.
- If a **geometry\_\_triangle** is used in 3D, the normal is in direction of the outer product  $v_{01} * v_{02}$  where  $v_{01}$  is the vector from node 0 to node 1 and  $v_{02}$  is the vector from node 0 to node 2.
- If a **geometry\_\_quadrilateral** is used in 3D, the normal is in direction of the outer product  $v_{01} * v_{02}$  where  $v_{01}$  is the vector from node 0 to node 1 and  $v_{02}$  is the vector from node 0 to node 2. Only non-distorted quadrilaterals should be used.

This normal can be switched sign by setting the **contact\_\_target\_\_geometry\_\_switch** with the same *index* to **-yes**.

In stead of geometries, also contact with target elements will be checked. Only contact with the elements **-bar2**, **-quad4**, and **-hex8** can be detected. Specify **contact\_\_target\_\_element\_\_group** for this.

The time steps should be such small, that contacting nodes penetrate the other elements only in small steps.

If a **contact\_\_target\_\_geometry** is used, then the contacting node should also be within the tolerance of the geometrical entity to be noticed!

If contact is detected, normal contact forces of size *contact\_penalty\_velocity* \* penetration are generated between the contacting node and the other element. Moreover, also a frictional force of size *friction* \* normal force is generated (see **contact\_\_plasti\_\_friction**).

With contact you need more iterations the normal, say 5 or more. See **control\_\_timestep\_\_iterations** how to define the number of iterations.

#### 6.107 **contact\_\_target\_\_geometry\_\_switch** *index switch*

See **contact\_\_target\_\_geometry**.

#### 6.108 **control\_\_bounda\_\_relax** *index switch*

With this **control\_\_bounda\_\_relax** you can require Tochnog to store the nodal right-hand-sides; for example external nodal forces for nodes with prescribed velocities. These

stored nodal right-hand-sides can later be used to relax prescribed boundary conditions; for example a prescribed velocity is removed and substituted by the stored external right-hand-side (external force) and slowly set to zero by multiplication with a time function as specified with **bounda\_force** in combination with **bounda\_time**. With the **control\_bounda\_relax\_geometry** record with the same index you can select a specific geometry for which the storing will be done.

A typical example can be found in the **relax1.dat** file in your distribution.

#### 6.109 **control\_bounda\_relax\_geometry** *index geometry\_item\_name geometry\_item\_index*

See **control\_bounda\_relax**.

#### 6.110 **control\_change\_dataitem\_apply** *index switch*

If *switch* is set to **-no**, any **change\_dataitem\*** data in the input file will be ignored. This is done for timestep records with the same index.

#### 6.111 **control\_check\_data** *index switch*

If *switch* is set to **-yes** the in-core database is checked at some moments during the calculation, for the specified control index. You can try this option in case you experience unexpected behavior.

#### 6.112 **control\_contact\_apply** *index switch*

If *switch* is set to **-yes**, the contact algorithm is used. If *switch* is set to **-no**, the contact algorithm is not used. This is done for timestep records with the same index.

Default *switch* is set to **-yes**. See also **contact\_apply**.

#### 6.113 **control\_convection\_apply** *index switch*

If *switch* is set to **-yes**, the convection of a material with respect to the mesh is allowed. If *switch* is set to **-no**, the convection of a material with respect to the mesh is not allowed. This is done for timestep records with the same index. See also **convection\_apply**.

**6.114 control\_data\_activate** *index data\_item\_name\_0 data\_item\_name\_1 ... switch*

With this record you can set data items to become activated if *switch* is set to **-yes** or de-activated if *switch* is set to **-no**. The *data\_item\_name* specifies a data record name.

**6.115 control\_data\_arithmetic** *index data\_item\_name data\_item\_index data\_item\_number operat*

This record allows you to change a data item. With *data\_item\_name data\_item\_index data\_item\_number* you select which data item to change. It will be changed with value *val* as specified in the corresponding **control\_data\_arithmetic\_double** record. With *operat* you select how to change the data item; possibilities are **-plus**, **-minus**, **-multiply** and **-divide**.

In stead of a specific index *data\_item\_index* you can also specify a range **-ra ... -ra**.

In case you specify **-all** for *data\_item\_number* the specified value will be used for all numbers of the record.

**6.116 control\_data\_arithmetic\_double** *index val*

See **control\_data\_arithmetic**.

**6.117 control\_data\_copy** *index data\_item\_from data\_item\_to*

Copy data item *data\_item\_from* to *data\_item\_to*. The user is responsible to apply only logic copy actions.

Normally the *data\_item\_from* and *data\_item\_to* should have the same length. As a special option however, you can copy **node\_inertia** to **node\_force** records, while using a **control\_data\_copy\_factor** of -1. This allows you to substitute material mass inertia by static nodal forces, for the remainder of the calculation. This in fact is the d'alembert principle.

**6.118 control\_data\_copy\_factor** *index factor*

Multiplication factor for **control\_data\_copy**.

**6.119 control\_data\_copy\_index** *index data\_item\_from index\_from data\_item\_to index\_to*

Copy data item *data\_item\_from* with index *index\_from* to *data\_item\_to* with *index\_to*. The user is responsible to apply only logic copy actions.

**6.120 control\_data\_copy\_index\_factor** *index factor*

Multiplication factor for **control\_data\_copy\_index**.

**6.121 control\_data\_delete** *index data\_item\_name index\_range*

Delete one or more data items. The *index\_range* is a number (e.g. 3) or a range (-**ra** ... -**ra**, or -**all**).

If *index data\_item\_name* is a nodal item (for example **node** or **node\_dof**) then *index\_range* can also be a geometrical entity (for example -**geometry\_line 1** or so), and the item will be deleted for nodes located on the geometrical entity.

If *index data\_item\_name* is a element item then *index\_range* can also be a geometrical entity (for example -**geometry\_line 1** or so), and the item will be deleted for elements with all nodes located on the geometrical entity.

In the example below element 1-10 and nodes 1-100 are deleted after some time in the calculation; this simulates dismantling a part of a structure somewhere in its lifetime. First, time steps with the total structure are taken; then a part of the structure is dismantled; then time steps with the remaining part of the structure are taken.

```
...
control_timestep 10 ...
...
control_data_delete 20 -element -ra -from 1 -to 10 -ra
control_data_delete 21 -node -ra -from 1 -to 100 -ra
...
control_timestep 30 ...
...
```

If an element or node is deleted, then also the corresponding records will be deleted. See also **control\_data\_put**.

### 6.122 **control\_data\_put** *index data\_item\_name index\_range number\_0 number\_1 ...*

Puts one or more data items.

The *index\_range* is a number (e.g. 3) or a range (**-ra ... -ra**, or **-all**). The **-all** option for *index\_range* is only available for nodal data items (like **node** or **node\_dof**). If *data\_item\_name* is a nodal item then *index\_range* can also be a geometrical entity (for example **-geometry\_line 1** or so), and the item will be put for nodes located on the geometrical entity. If *data\_item\_name* is a element item then *index\_range* can also be a geometrical entity (for example **-geometry\_line 1** or so), and the item will be put for elements with all nodes located on the geometrical entity.

With *number\_0 number\_1* etc. you can set which value should be put. For example only using 3 for *number\_0* then you only want to set the fourth value for the data item (remember that numbering starts at 0). To specify the numbers for dof's you can also specify names like **-velx**, **-sigxx**, etc. In case you specify **-all**, then all values should be given in **control\_data\_put\_double** or **control\_data\_put\_integer**.

The values to be put should be specified in a **control\_data\_put\_double** record for real data or in a **control\_data\_put\_integer** record otherwise. You should specify a value for each and every specified number.

If the data item already exists it is overwritten; else a new record will be generated.

See also **control\_data\_delete**.

### 6.123 **control\_data\_put\_double** *index ...*

See **control\_data\_put**.

### 6.124 **control\_data\_put\_integer** *index ...*

See **control\_data\_put**.

### 6.125 **control\_data\_save** *index switch*

If *switch* is set to **-yes** save the status of strains, stresses, displacements, etc. At a later point in the calculation you can plot with gid data relative to these saved data with **control\_print\_gid\_save\_difference**.

...

```

control__timestep 10 ...
...
control__data__save 20 -yes
...
control__timestep 30 ...
...
control__print__gid 40 -separate__sequential
control__print__gid__save__difference 40 -yes
...

```

### 6.126 **control\_\_dependency\_\_apply** *index switch*

If *switch* is set to **-yes**, dependencies as specified with **dependency\_\_diagram** and **dependency\_\_item** are included in the calculation. If *switch* is set to **-no**, these dependencies are not included. This is done for timestep records with the same index.

Default, if **control\_\_dependency\_\_apply** is not specified, then **dependency\_\_apply** will be used.

### 6.127 **control\_\_distribute** *index distribution\_\_type data\_\_item\_\_name data\_\_item\_\_index data\_\_item\_\_number*

Apply a random number, based on a **-lognormal** or **-normal** distribution, to the *data\_\_item\_\_name* records. This is done for the index *data\_\_item\_\_index* and the *data\_\_item\_\_number* value in those records (0 for the first value, 1 for the second value, etc.). The *data\_\_item\_\_index* can optionally be set to **-all** in stead of a specific index, so that the distribution will be applied to all existing indices.

The *distribution\_\_type* should be set to **-lognormal** or **-normal**. Use the **control\_\_distribute\_\_parameters** record to set the mean value and standard deviation.

The *data\_\_item\_\_name* can be one of **group\_\_\*** or **node\_\_\***. If you specify a **group\_\_\***, for example **group\_\_materi\_\_elasti\_\_young** or so, then not the group item record self will be changed, but the item will be changed for the elements which use this record; in this way you can give a random distribution to group data like Young modulus, plastic properties, etc.

It is optionally possible to require a distribution that is correlated in space. To obtain such a correlated distribution, you need to specify the **control\_\_distribute\_\_correlation\_\_length** record. If the specified correlation length is larger than 1.e12 then Tochnog uses a constant *G* (all components have the same value). As a special option, you can specify a different distribution length in each space direction (in 2D specify 2 values, and in 3D specify 3 values).

With **control\_\_distribute\_\_correlation\_\_distance** you can set the maximum distance

below which data will be correlated. Above that distance tochnog will not correlate the data. Default, if **control\_distribute\_correlation\_distance** is not specified it will be taken to be 4 times the correlation length.

With **control\_distribute\_minimum\_maximum** you can set the minimum and maximum value which the random numbers are allowed to take. Numbers outside that range will be cutoff to the minimum or maximum value. A typical application would be limiting the void ratio to a range which is needed by a hypoplasticity law.

In the first example, an lognormal distribution with average 100 and standard deviation 1.2 is used to the nodal temperatures:

```
...
materi_velocity
condif_temperature
...
control_distribute 10 -lognormal -node_dof -all -temp
control_distribute_parameters 10 100. 1.2
...
```

In the second example, a normal distribution with average 1 and standard deviation 1.e-3 is used to the y coordinate of the nodes:

```
...
control_distribute 10 -normal -node -all 1
control_distribute_parameters 10 1. 1.e-3
...
```

In the third example, a normal distribution with average 10 and standard deviation 1. is used to the young's modulus of group 7:

```
...
control_distribute 10 -normal -group_materi_elasti_young 7 0
control_distribute_parameters 10 10. 1.
...
```

This **control\_distribute\_\*** is presently only available on linux computers. The **control\_distribute\_\*** should be before all **control\_reset\_dof** (thus have a higher index).

**6.128 control\_distribute\_correlation\_distance** *index maximum\_distance*

**6.129 control\_distribute\_correlation\_length** *index correlation\_length*  
...

See **control\_distribute**.

**6.130 control\_distribute\_minimum\_maximum** *index minimum maximum*

See **control\_distribute**.

**6.131 control\_distribute\_parameters** *index mean\_value standard\_deviation*

See **control\_distribute**.

**6.132 control\_distribute\_seed** *index seed*

For experts only. With this record you can specify the seed which will be used to start the random series of numbers. Use a positive integer value.

As a special option you can set *seed* to **-new** then Tochnog will self choose a seed. As a special option you can set *seed* to **-old** then Tochnog will use the previous seed.

**6.133 control\_element\_group** *index switch*

If *switch* is set to **-yes** the records **area\_element\_group** will be evaluated for the current control index. This option should not be used if the control index is also used for timesteps.

**6.134 control\_element\_group\_apply** *index number*

See **element\_group\_apply**.

**6.135 control\_geometry\_moving** *index -initialise*

Initialise all **geometry\_moving** records. That is, determine for all elements at which time they will be excavated by the **geometry\_moving** entities in the remainder of the calculation.

### 6.136 **control\_groundflow\_consolidation\_apply** *index switch*

If *switch* is set to **-no**, then the material divergence part in the groundflow equation is skipped.

Attention: If you want consolidation in geotechnics then set the *switch* to **-yes**. If you do not want consolidation in geotechnics then set the *switch* to **-no**.

This is done for timestep records with the same index.

Default, if **control\_groundflow\_consolidation\_apply** is not specified, then **groundflow\_consolidation\_apply** will be used.

### 6.137 **control\_groundflow\_nonsaturated\_apply** *index switch*

If *switch* is set to **-no**, then nonsaturated groundflow data (eg van Genuchten) will not be applied; only saturated data will be used.

Default, if **control\_groundflow\_nonsaturated\_apply** is not specified, then **groundflow\_nonsaturated\_apply** will be used.

### 6.138 **control\_inertia\_apply** *index switch\_0 switch\_1 ...*

If *switch\_0* is set to **-yes**, the corresponding inertia term is included (material mass, heat capacity, ..). The same for the other switches. A switch should be specified for each of the principal dof's. See the 'input file - data part - introduction - types of dof's' section for an explanation about principal dof's. The sequence of the principal dof's is in the order as initialised in the **initia ... end\_initia** part.

As a special option you can specify only one switch, and then the specified value will automatically be used for all principal dof's.

This **control\_inertia\_apply** record is applied for timestep records with the same index.

Default, if **control\_inertia\_apply** is not specified, then **inertia\_apply** will be used.

### 6.139 **control\_input** *index switch*

If *switch* is set to **-yes** Tochnog reads an extra piece of input from the file *index.dat*. The piece of input needs to be closed by two **end\_data** statements. Comments ( ... ) are not allowed. All defines and arithmetics cannot be used.

#### 6.140 **control\_materi\_damage\_apply** *index switch*

If *switch* is set to **-no**, any damage data in the input file will be ignored. This is done for timestep records with the same index.

This option is convenient for testing your input file just linear, without the need to outcomment each and every part with damage data. See also **materi\_damage\_apply**.

#### 6.141 **control\_materi\_dynamic** *index factor*

Same as **materi\_dynamic** but now only for timesteps with the same control index.

#### 6.142 **control\_materi\_elasti\_k0** *index switch*

See **group\_materi\_elasti\_k0**.

#### 6.143 **control\_materi\_failure\_apply** *index switch*

If *switch* is set to **-no**, any damage data in the input file will be ignored. This is done for timestep records with the same index.

This option is convenient for testing your input file just linear, without the need to outcomment each and every part with failure data. See also **materi\_failure\_apply**.

#### 6.144 **control\_materi\_plasti\_hypo\_masin\_ocr\_apply** *index switch*

If *switch* is set to **-yes** the OCR will be applied. If *switch* is set to **-no** the OCR will not be applied.

Default *switch* is **-no**.

#### 6.145 **control\_materi\_plasti\_hypo\_masin\_clay\_ocr\_apply** *index switch*

If *switch* is set to **-yes** the OCR will be applied. If *switch* is set to **-no** the OCR will not be applied.

Default *switch* is **-no**.

#### 6.146 **control\_materi\_plasti\_hardsoil\_gammap\_initial** *index switch*

See theory section on hardsoil.

#### 6.147 **control\_materi\_plasti\_hypo\_pressure\_dependent\_void\_ratio** *index switch*

If *switch* is set to **-yes** the initial void ratio is corrected for pressure dependency; see the theory section. This is done for the first timestep in the corresponding **control\_timestep** record with the same *index*. Default *switch* is set to **-no**.

#### 6.148 **control\_materi\_plasti\_hypo\_niemunis\_visco\_ocr\_apply** *index switch*

If *switch* is set to **-yes** the OCR will be applied. If *switch* is set to **-no** the OCR will not be applied.

Default *switch* is **-no**.

#### 6.149 **control\_materi\_plasti\_hypo\_substepping** *index switch*

If *switch* is set to **-yes** substepping will be applied in hypoplasticity routines. If *switch* is set to **-no** substepping will not be applied in hypoplasticity routines.

If this record is not specified the record **materi\_plasti\_hypo\_substepping** will be used.

#### 6.150 **control\_materi\_plasti\_tension\_apply** *index switch*

If *switch* is set to **-no**, any tension-plasticity data in the input file will be ignored. This is done for timestep records with the same index.

See also **materi\_plasti\_tension\_apply**.

#### 6.151 **control\_materi\_plasti\_visco\_apply** *index switch*

If *switch* is set to **-no**, any visco-plasticity data in the input file will be ignored. This is done for timestep records with the same index. See also **materi\_plasti\_visco\_apply**.

### 6.152 **control\_materi\_updated\_apply** *index switch*

If *switch* is set to **-no**, any **-updated** material memory will be set to **-updated\_linear**. If *switch* is set to **-yes**, any non-specified material memory will be set to **-updated**. This is done for timestep records with the same index.

### 6.153 **control\_materi\_undrained\_apply** *index switch*

See **group\_materi\_undrained\_capacity**. Default, if **control\_materi\_undrained\_apply** is not specified, *switch* is set to **-yes**.

### 6.154 **control\_materi\_viscosity\_apply** *index switch*

If *switch* is set to **-no**, any viscosity in the input file will be ignored. This is done for timestep records with the same index.

### 6.155 **control\_mesh\_activate\_gravity\_apply** *index index\_0 index\_1* ...

With this record you can specify which of the **mesh\_activate\_gravity\_\*** records should be applied, by specifying the indices of the records that should be applied. In case this **control\_mesh\_activate\_gravity\_apply** is not given, all **mesh\_activate\_gravity\_\*** records will be applied. As a special option you can use **-all** indicating that all of the **mesh\_activate\_gravity\_\*** records should be applied (this is the same as not specifying the **control\_mesh\_activate\_gravity\_apply** record at all). As another special option you can use **-none** indicating that none of the **mesh\_activate\_gravity\_\*** records should be applied.

See also **mesh\_activate\_gravity\_time**.

### 6.156 **control\_mesh\_adjust\_geometry** *index geometry\_entity\_item\_0* *geometry\_entity\_index\_0 geometry\_entity\_item\_1* *geometry\_entity\_index\_1*

The nodes of the geometry entity 0 are replaced such that they neatly follow the boundary of geometry 1. In this way, it is easy to make a mesh with elements precisely in specific regions, if this is required to give separate **element\_group** data (e.g. materials) to the geometry and it is too difficult to make the mesh at once OK for this.

The created mesh may be quite distorted.

### 6.157 **control\_mesh\_change\_element\_group** *index element\_group\_0 element\_group\_1*

Change the group number **element\_group** of elements from *element\_group\_0* to *element\_group\_1*. The index should not be equal to a timestep index.

### 6.158 **control\_mesh\_convert** *index switch*

If *switch* is set to **-yes**, tochnog will automatically convert elements:

- **-bar2** in 2D to **-quad4** if the element is an interface
- **-bar3** in 2D to **-quad6** if the element is an interface
- **-tria3** in 3D to **-prism6** if the element is an interface
- **-tria6** in 3D to **-prism12** if the element is an interface
- **-quad4** in 3D to **-hex8** if the element is an interface
- **-quad8** in 2D to **-quad6** if the element is an interface
- **-quad8** in 3D to **-hex18** if the element is an interface
- **-quad9** in 2D to **-quad6** if the element is an interface
- **-quad9** in 3D to **-hex18** if the element is an interface
- **-hex20** in 3D to **-hex18** if the element is an interface
- **-hex20** in 3D to **-hex27** if the element is not an interface
- **-prism15** in 3D to **-prism12** if the element is an interface
- **-prism15** in 3D to **-prism18** if the element is not an interface

For an interface you need to specify interface data in the **group\_interface....** For example the **-bar2** is connected to two nodes, whereas the converted **-quad4** is connected to four nodes. In a similar manner all other converted elements also get extra nodes. This options makes it easy to obtain a mesh with interface elements. For example generate with GID in a 2d mesh bar elements, insert group data, and use **control\_mesh\_convert** to generate the interface elements. This generation of interfaces only works properly if certain conditions are satisfied:

- Each interface needs to have only isoparametric neighbours which have a total side in common with the interface. For example a **-hex8** interface should only have **-hex8** neighbours.

- Surfaces with interface elements should not intersect with another surface with interface elements.

The new generated nodes will be connected to existing neighbouring element at the interfaces. The **control\_mesh\_convert** tries to do that automatically correct. You can help however by specifying in the record **control\_mesh\_convert\_element\_group** element groups which are located at one side of the interfaces (for example the groups of a pile in soil when an interface is generated between pile and soil).

Example in which a **-bar2** interface becomes a **-hex8** interface:

```
...
number_of_space_dimension 3
...
end_initia
...
element 1 -bar2 101 102
element_group 1 10
...
group_interface 10 -yes
...
control_mesh_extrude 100 ...
...
control_mesh_convert 110 -yes
...
```

If *switch* is set to **-no**, tochnog will not convert elements.

**6.159 control\_mesh\_convert\_element\_group** *index element\_group\_0*  
*element\_group\_1 ...*

See **control\_mesh\_convert**.

**6.160 control\_mesh\_convert\_quad9\_quad6** *index dir*

Convert **quad9** into **quad6** is a 2D calculation. With *dir* you can decide in which isoparametric direction of the **quad9** nodes should be deleted (so that becomes the linear direction in the **quad6** element). Set *dir* either to **-x** or to **-y**.

#### 6.161 **control\_mesh\_convert\_tria6\_tria3** *index switch*

Convert **tria6** into **tria3** is a 2D calculation. This is done if *switch* is set to **-yes**.

#### 6.162 **control\_mesh\_copy** *index move\_x move\_y move\_z*

This option copies the mesh. Thus you get twice as much elements and nodes. Each new node is moved *move\_x move\_y move\_z* relative to the corresponding old node. In 1d you only should specify *move\_x*. In 2d you only should specify *move\_x move\_y*.

#### 6.163 **control\_mesh\_cut\_geometry** *index geometry\_item\_name geometry\_item\_index*

This command cuts away a part of the mesh, as defined by *geometry\_item\_name geometry\_item\_index*. The cut away mesh can be substituted by its nodal forces. Actually, with **control\_mesh\_cut\_force** you can set for each direction if the nodal force of the cut away mesh should be applied to the remaining mesh. This will be done if you set the corresponding *switch* in **control\_mesh\_cut\_force** to **-yes**. In 2D you should set two switches, and in 3D you should set 3 switches.

See **mesh\_cut\_1.dat** and **mesh\_cut\_2.dat** in the test directory for examples. See **earthquake\_2.dat** how this **control\_mesh\_cut\_geometry** command can save you computing time in dynamic calculations with many timesteps.

#### 6.164 **control\_mesh\_cut\_force** *index switch\_0 switch\_1 switch\_2*

See **control\_mesh\_cut\_geometry**.

#### 6.165 **control\_mesh\_delete\_element** *index number\_0 number\_1 ...*

The elements with numbers *number\_0 number\_1* will be deleted. Otherwise the same as **control\_mesh\_delete\_geometry**.

#### 6.166 **control\_mesh\_delete\_geometry** *index geometry\_entity\_item geometry\_entity\_index*

All elements which are part of the geometry item are deleted. In this way, it is easy to make a mesh with holes, tunneling systems in ground, etc. Remaining nodes in the geometry, are moved onto the edge of the geometry if the corresponding **control\_mesh\_delete\_geometry\_move\_node**

record with the same index is set to **-yes**; (otherwise, the remaining nodes are left inside the geometry).

For a **geometry\_point**, elements inside the tolerance distance of the point will be deleted. For a **geometry\_circle**, elements in the total inner area of the circle radius plus its tolerance will be deleted. Likewise for other geometries.

If you combine this record with a **control\_timestep** record, then the element will be slowly deleted, starting from a complete element at the start of the timestep up to no element at the end of the timestep. This is accomplished by reducing the nodal forces of the elements slowly to zero; at the end of the timestep, the element is deleted completely. This might be useful for a better convergence behavior of the iterative process.

If an element is being deleted, **element\_empty** is automatically set to **-empty**, even if the element is not completely deleted yet. This allows you to look with GID 'behind elements that are being deleted' (see also **element\_empty** and **control\_print\_gid\_empty**).

See also **control\_mesh\_delete\_geometry\_move\_node**, **control\_mesh\_delete\_geometry\_element** and **control\_mesh\_delete\_geometry\_element\_group**.

#### 6.167 **control\_mesh\_delete\_geometry\_direct** *index switch*

If *method* is set to **-yes** the elements inside the geometry will be deleted direct, as opposed to slowly over the timesteps.

#### 6.168 **control\_mesh\_delete\_geometry\_element** *index element\_name\_0 element\_name\_0 ...*

Only elements with names *element\_name\_0* etc. will be deleted if the **control\_mesh\_delete\_geometry** (with the same index) is used. For example, *element\_name\_0* is **-quad4**, **-beam**, etc.

If this record is not specified all elements in the geometry will be deleted.

#### 6.169 **control\_mesh\_delete\_geometry\_element\_group** *index element\_group\_0 element\_group\_1 ...*

Only elements from group *element\_group\_0* etc. will be deleted if the **control\_mesh\_delete\_geometry** (with the same index) is used.

**6.170 control\_mesh\_delete\_geometry\_factor** *index factor\_0 factor\_1*  
...

The elements deleted by **control\_mesh\_delete\_geometry** (with the same index), will be deleted by a factor *factor\_0* at the start of the timesteps up to a factor *factor\_1* at the end of the timesteps. If the **control\_mesh\_delete\_geometry** is not used in combination with timesteps, then directly *factor\_1* will be applied.

If *factor\_1* exceeds  $1. - 1.e - 10$  an element will be completely deleted from the calculation, that is the **element** record will be removed and cannot be reactivated in any way later in the calculation.

If this record is not specified then *factor\_0* = 0 and *factor\_1* = 1.

**6.171 control\_mesh\_delete\_geometry\_method** *index method*

Determines the condition on which an element will be considered part of the geometry to be deleted. If *method* is set to **-all** then all element nodes should be part of the geometry. If *method* is set to **-any** then any of the element nodes should be part of the geometry. If *method* is set to **-average** then the average element coordinate should be part of the geometry.

Default this record is **-all**.

See also **control\_mesh\_delete\_geometry**.

**6.172 control\_mesh\_delete\_geometry\_move\_node** *index switch*

Determines if remaining nodes inside a deleted geometry, are moved onto the edge of the geometry (**-yes**) or not (**-no**). Moving nodes makes that the element mesh exactly fits the deleted geometry, but may also lead to heavily distorted elements. Default this record is **-no**.

See also **control\_mesh\_delete\_geometry**.

**6.173 control\_mesh\_delete\_geometry\_projection\_type** *index type*

This record allows you to control what geometry will actually be deleted. Set *type* to **-project\_inside** or **-project\_exact**. For example if the geometry is a **geometry\_circle** then **-project\_inside** means that everything inside the circle will be deleted, whereas **-project\_exact** means that everything within a tolerance from the circle edge will be deleted. Default *type* is **-project\_exact**.

#### 6.174 **control\_mesh\_delete\_geometry\_stop** *index switch*

If *switch* is set to **-yes**, any deleting of elements in geometries will be stopped. That is, all remaining delete factors from **control\_mesh\_delete\_geometry\_factor** will be destroyed and all elements will become fully active again.

In combination with **global\_element\_dof\_apply -yes**, the elements which become active again will take their strains, stresses etc. of the moment just before being deleted! If you want to lower the stresses or strains or so, then consider using **control\_reset\_dof**.

In combination with **global\_element\_dof\_apply -no**, the elements which become active again will take their strains, stresses etc. from the nodes.

#### 6.175 **control\_mesh\_delete\_geometry\_stop\_geometry** *index geometry\_entity\_name geometry\_entity\_index*

Only do the **control\_mesh\_delete\_geometry\_stop** for elements part of the geometrical entity specified in this **control\_mesh\_delete\_geometry\_stop\_geometry**.

#### 6.176 **control\_mesh\_delete\_small** *index eps*

At the end of a timestep, an element will be deleted when its volume has become smaller than *eps*.

#### 6.177 **control\_mesh\_duplicate\_element\_group** *index element\_group\_old element\_group\_new*

Use this command to duplicate elements from group *element\_group\_old* to new elements with group *element\_group\_new*. The new elements get the same nodes as the old original elements.

#### 6.178 **control\_mesh\_element\_group\_apply** *index group\_0 group\_1 ...*

If you specify this record, only the element groups specified will be evaluated in the timesteps with the same index. Default, if **control\_mesh\_element\_group\_apply** is not specified, all elements groups will be used.

### 6.179 **control\_mesh\_extrude** *index z0 z1 z2 ...*

Option to extrude a 2D mesh to 3D. The 2D mesh has x,y,z coordinates, with z=0. The 3D mesh will have x,y,z coordinates. You need to specify in the initialisation part **number\_of\_space\_dimensions** to 3.

With z0, z1, z2 etc. you specify the coordinates of the layers to which the 2D coordinates will be extruded. With n0, n1, n2 you specify the number of elements that will be generated in each layer; n0 specifies the number of elements between z0 and z1, n1 specifies the number of elements between z1 and z2, etc.; for the last n-value you always should use a 1 (this is a dummy value, that is not used for any layer at all).

Extrusion must be done before doing mesh refinements, mesh splitting, etc.

### 6.180 **control\_mesh\_extrude\_direction** *index dir*

Default extrusion is done in the global z-direction. Optionally you can set *dir* to -y and then extrusion is done in global y-direction.

### 6.181 **control\_mesh\_extrude\_element** *index name*

If you extrude **-tria6** elements, you can set *name* either to **-prism12** or **-prism18**. Then either the 12 node or 18 node prismatic elements will be generated. Default, if this **control\_mesh\_extrude\_element** is not set, then **-prism18** is used for *name*.

See also **control\_mesh\_extrude\_n**.

### 6.182 **control\_mesh\_extrude\_contact\_spring\_element\_group** *index element\_group\_0 element\_group\_1 ...*

See **control\_mesh\_extrude\_contact\_spring\_element\_group\_new**.

### 6.183 **control\_mesh\_extrude\_contact\_spring\_element\_group\_new** *index element\_group\_new\_0 element\_group\_new\_1 ...*

If this record is specified, then a contact spring is generated between each start node and end node in the extrude direction. This option comes handy, when you want to use these contact springs to enforce that the nodes on the start plane get the same displacements as the nodes on the end plane, which models that the extruded mesh is in fact part of a very long domain with no variations in the longitudinal direction of the domain.

The contact springs get group number *element\_group\_new\_0* when its node is attached to an element with old group *element\_group\_0*. The contact springs get group number *element\_group\_new\_1* when its node is attached to an element with old group *element\_group\_1*. Etc. The old groups are specified in the **control\_mesh\_extrude\_contact\_spring\_element** record. If the contact spring's node is attached to more than one old group, the first specified old group, and corresponding new group, will be used.

As a special option, if you specify in **control\_mesh\_extrude\_contact\_spring\_element\_group\_new** only one new element group number, then all contact springs will be placed on that group.

**6.184 control\_mesh\_extrude\_element\_group\_new** *index element\_group\_old\_0 element\_group\_old\_1 ... element\_group\_new\_00 element\_group\_new\_01 ... element\_group\_new\_10 element\_group\_new\_11 ...*

With this option you set the *element\_group* number of the new extruded elements.

With *element\_group\_old\_0*, *element\_group\_old\_1* etc. you specify the old *element\_group* numbers of the 2D elements (which will be extruded). For these old groups, you specify for each layer in z-direction what the new *element\_group* numbers of the extruded 3D elements should be. For example, *element\_group\_new\_00*, *element\_group\_new\_01* etc. give for *element\_group\_old\_0* what the *element\_group* numbers of the new extruded elements will be (for each z layer).

You need to specify *element\_group* numbers for each and every z layer.

If a new element group is set to a negative number in this **control\_mesh\_extrude\_element\_group\_new** the elements will not be generated.

See also **control\_mesh\_extrude**.

**6.185 control\_mesh\_extrude\_n** *index n0 n1 n2 ...*

See **control\_mesh\_extrude**.

**6.186 control\_mesh\_generate\_beam** *index element\_group geometry\_entity\_item geometry\_entity\_index*

The same as **control\_mesh\_generate\_truss**, now for beams however.

**6.187 control\_mesh\_generate\_contact\_spring** *index element\_group geometry\_entity\_item geometry\_entity\_index*

Generate **-contact\_spring2** springs for nodes which have the same position in space. This can be used to connect these nodes with spring elements, so to model a contact area. Only nodes located on the specified geometry entity will be used.

The generated springs will get an **element\_group** record with value *element\_group*. So in that element group you can put the properties of the contact springs.

With the **control\_mesh\_generate\_contact\_spring\_element** record you can set between which elements the contact\_springs should be generated. For example use **-quad4** and **-truss\_beam** if you want to generate contact\_springs between those elements.

If **control\_mesh\_generate\_contact\_spring\_element\_group** (with the same index) is used, contact springs will only be generated between elements of the groups *element\_group\_0*, *element\_group\_1* etc.

**6.188 control\_mesh\_generate\_contact\_spring\_element** *index element\_0 element\_1*

See **control\_mesh\_generate\_contact\_spring**.

**6.189 control\_mesh\_generate\_contact\_spring\_element\_group** *index element\_group\_0 element\_group\_1 ...*

See **control\_mesh\_generate\_contact\_spring**.

**6.190 control\_mesh\_generate\_interface** *index element\_group\_0 element\_group\_00 element\_group\_01 element\_group\_1 element\_group\_10 element\_group\_11 ...*

With this record you can generate interface elements.

The interface elements will be given an **element\_group** record *element\_group\_0* if the interface is between *element\_group\_00* and *element\_group\_01*. The interface elements will be given an **element\_group** record *element\_group\_1* if the interface is between *element\_group\_10* and *element\_group\_11*. The interface elements will be given an **element\_group** record *element\_group\_2* if the interface is between *element\_group\_20* and *element\_group\_21*. Etc, etc.

The groups *element\_group\_00*, *element\_group\_10*, *element\_group\_20*, etc. should be on one side. The groups *element\_group\_01*, *element\_group\_11*, *element\_group\_21*, etc.

should be on the opposite side.

Between two linear 2d elements **-quad4** interfaces will be generated. Between two quadratic 2d elements **-quad6** interfaces will be generated. Between two **-hex8** elements a **-hex8** interface will be generated. Between two **-hex27** elements a **-quad18** interface will be generated. Between two **-tet4** elements a **-prism6** interface will be generated. Between two **-tet10** elements a **-tria12** interface will be generated. Between two **-prism6** elements a **-prism6** interface will be generated on sides with 3 nodes. Between two **-prism6** elements a **-hex8** interface will be generated on sides with 4 nodes. For other situations no interface element will be generated.

Crossing interfaces are not allowed, eg in 2d you should not have locally two connecting lines with interfaces and in 3d you should not have locally two connecting surfaces with interfaces.

Interfaces can only be generated between exactly two elements. You cannot generate interface where three elements connect; for example you cannot generate an interface at the common side of two quad4 elements if there is also a truss along that common side.

If you want the interface to connect, you really should do for example:

```
...
control_mesh_generate_interface 10 20 30 31 20 40 41
...
```

which takes care that the interfaces generated by this command are connected together. If you would have used the following:

```
...
control_mesh_generate_interface 10 20 30 31
control_mesh_generate_interface 11 20 40 41
...
```

The interfaces generated by the two commands will not connect.

See also **control\_mesh\_generate\_interface\_geometry** and **control\_mesh\_generate\_interface\_method**

#### 6.191 **control\_mesh\_generate\_interface\_geometry** *index geometry\_item\_name geometry\_item\_index*

Restrict the generation of interfaces for the **control\_mesh\_generate\_interface** record with the same index to the geometry specified in this **control\_mesh\_generate\_interface\_geometry** record.

### 6.192 **control\_mesh\_generate\_interface\_method** *index method\_select method\_generate*

If you set *method\_select* to **-element\_geometry** the **control\_mesh\_generate\_interface** will select with **element\_geometry** between which elements interfaces will be generated.

If you set *method\_generate* to **-element\_geometry** the **control\_mesh\_generate\_interface** will generate **element\_geometry** records for the interface elements, in stead of **element\_group** records.

So for example using **-element\_geometry -element\_geometry** tells that the **control\_mesh\_generate\_interface** in fact is *index element\_geometry\_0 element\_geometry\_00 element\_geometry\_01 element\_geometry\_1 element\_geometry\_10 element\_geometry\_11*  
....

Default, if **control\_mesh\_generate\_interface\_method** is not specified, it is set to **-element\_group -element\_group**.

### 6.193 **control\_mesh\_generate\_spring1** *index element\_group geometry\_entity\_item geometry\_entity\_index*

Generate **-spring1** springs for nodes. Only nodes located on the specified geometry entity will be used.

The generated springs will get an **element\_group** record with value *element\_group*. So in that element group you can put the properties of the springs (see **group\_spring\_stiffness** etc.).

### 6.194 **control\_mesh\_generate\_spring2** *index element\_group geometry\_entity\_item geometry\_entity\_index*

Generate **-spring2** springs for nodes which have the same position in space. This can be used to connect these nodes with spring elements. Only nodes located on the specified geometry entity will be used.

The generated springs will get an **element\_group** record with value *element\_group*. So in that element group you can put the properties of the springs (see **group\_spring\_stiffness** etc.).

Typically you can use this option to connect meshes which were generated with different **control\_mesh\_macro** records or so.

If you need interfaces, then afterwards use a **control\_mesh\_convert** to turn the generated surface elements into real interface elements.

**6.195 control\_mesh\_generate\_truss** *index element\_group geometry\_entity\_item geometry\_entity\_index*

Generate trusses for nodes which are neighbor in space (that is, for nodes which are connected by an isoparametric finite element). Only nodes located on the specified geometry entity will be used.

The generated trusses will get an **element\_group** record with value *element\_group*. So in that element group you can put the properties of the trusses (see **group\_truss\_elasti\_young** etc.).

Typically you can use this option to put easy trusses somewhere in a mesh with isoparametric elements.

**6.196 control\_mesh\_generate\_truss\_beam** *index element\_group geometry\_entity\_item geometry\_entity\_index*

The same as **control\_mesh\_generate\_truss**, now for truss\_beams however.

**6.197 control\_mesh\_generate\_truss\_beam\_loose** *index switch*

This record works together with the **control\_mesh\_generate\_truss**, **control\_mesh\_generate\_beam** and **control\_mesh\_generate\_truss\_beam** records.

If *switch* is set to **-yes**, the truss or beam of truss\_beam will not be connected to the existing nodes, but new nodes will be generated for the generated element.

Afterwards you can typically connect the truss or beam of truss\_beam to the existing mesh with **contactsprings**, so that the end result is that you can model frictional slip between isoparametric elements and structural elements.

See also **control\_mesh\_generate\_contact\_spring**.

**6.198 control\_mesh\_generate\_truss\_beam\_macro** *index macro\_0 macro\_1 ...*

This record works together with the **control\_mesh\_generate\_truss**, **control\_mesh\_generate\_beam** and **control\_mesh\_generate\_truss\_beam** records.

With *macro\_0* etc. you can specify the indices of **control\_mesh\_macro\_\*** records. Then the trusses (or beams or truss\_beams) will only be generated for nodes coming from the mesh generated by the macro records with the specified indices.

This is handy in case you generate two neighboring meshes with macro's, and want to

generate the elements (trusses or beams or `truss_beams`) in between these two meshes. Normally, both the meshes would get the extra truss (or ..) in case you use a `geometry_line` or so to specify that the new elements should be generated between the two meshes (this is so, since the nodes of both meshes are located on the `geometry_line`). With the present **`control_mesh_generate_truss_beam_macro`** record however you can specify that the new elements should only be generated by looking at the nodes of some of the meshes, and so no double new elements will be generated in between the two meshes.

### 6.199 **`control_mesh_generate_truss_beam_separate`** *index switch*

This record works together with the **`control_mesh_generate_truss`**, **`control_mesh_generate_beam`** and **`control_mesh_generate_truss_beam`** records.

If *switch* is set to **-yes**, the truss or beam of `truss_beam` will be generated for separate regions, not necessary connected by isoparametric finite elements.

A typical example is the generation of exactly one truss between two end points (thus no trusses along all of the isoparametric elements between the end points). For this, put the end points in a geometry set, and also use **-yes** for this **`control_mesh_generate_truss_beam_separate`** record.

### 6.200 **`control_mesh_gid_batch`** *index switch*

If *switch* is set to **-yes** all **`mesh_gid_*`** records are used to generate elements using GiD as preprocessor. In fact, the GiD program is called from inside Tochnog as batch. This makes it convenient to do everything that you need from inside the Tochnog input file, without even opening GiD as preprocessor. A simple example is as follows:

```
echo -yes
number_of_space_dimensions 2
end_initia

( define points )
mesh_gid_point_coord 1 0. 0.
mesh_gid_point_coord 2 1. 0.
mesh_gid_point_coord 3 0. 1.
mesh_gid_point_coord 4 1. 1.

( define lines, each line connects to two points )
mesh_gid_line_point 1 1 2
mesh_gid_line_point 2 2 4
mesh_gid_line_point 3 4 3
mesh_gid_line_point 4 3 1

( define closed surfaces, each surfaces connects to multiple lines )
```

```

mesh_gid_surface_line 1 1 2 3 4
( define that the elements in this surface get a group number )
mesh_gid_surface_element_group 1 -yes

( size of elements to be generated )
mesh_gid_size 0.1

( call gid in batch, this generates an extra file index.dat so 10.dat in this example )
control_mesh_gid 10 -yes
( read the mesh in 10.dat )
control_input 10 -yes

( add extra data )
( ... )

end_data

```

A more complex example which creates a circular hole in a rectangular zone is as follows:

```

echo -yes
number_of_space_dimensions 2
end_initia

( the circle will be used hollow )
mesh_gid_circle_coord 1 0.5 0.5
mesh_gid_circle_radius 1 0.3
mesh_gid_circle_hollow 1 -yes

mesh_gid_point_coord 1 0. 0.
mesh_gid_point_coord 2 1. 0.
mesh_gid_point_coord 3 0. 1.
mesh_gid_point_coord 4 1. 1.

mesh_gid_line_point 1 1 2
mesh_gid_line_point 2 2 4
mesh_gid_line_point 3 4 3
mesh_gid_line_point 4 3 1

( the surface edges are the line of the circle and the 4 specified lines )
mesh_gid_surface_line 1 1 2 3 4 5
mesh_gid_surface_element_group 1 1

mesh_gid_size 0.05

control_mesh_gid 10 -yes
control_input 10 -yes

target_item 0 -node 10 1

```

```
target_value 0    0.8715 1.e-2
end_data
```

For more examples see in your distribution **test/other/mesh\_gid\_\*.dat**.

Attention: Please realise that when generating gid objects (circle, cylinder, etc) also automatically points, lines, surfaces and volumes are generated. So you get more points, lines, surfaces and volumes then you specify yourself with **mesh\_gid\_point\_coord**, **mesh\_gid\_line\_point**, **mesh\_gid\_surface\_line** and **mesh\_gid\_volume\_surface**. Thus, you need to pay attention to which point, line, surface and volume numbers you specify in **mesh\_gid\_line\_point**, **mesh\_gid\_surface\_line** and **mesh\_gid\_volume\_surface**. To help you, this option **control\_mesh\_gid\_batch** will print for all **mesh\_gid\_\*** data the points, lines, surfaces and volumes numbers that it generates. So for each thing that you specify you get the corresponding point, line and surface numbers. It is these printed numbers you should use in the records which need these numbers: **mesh\_gid\_line\_point**, **mesh\_gid\_surface\_line** and **mesh\_gid\_volume\_surface**!

Attention: When you specify group numbers for **mesh\_gid ...\_group** records, you should apply the numbers 1, 2, 3, etc for the groups, and don't use gaps in the numbers.

Attention: For this option to work you need to have GiD (of CIMNE) installed on your computer. Take care that the GiD path where the GiD executable is stored is set in your PATH environment symbol. Also take care that the **tochnog.gid** directory from your Tochnog distributions is copied to the GiD **problemtypes** directory.

### 6.201 control\_mesh\_interface\_triangle *index switch*

See **mesh\_interface\_triangle\_coordinates**.

### 6.202 control\_mesh\_keep\_element *index element\_0 element\_1 ...*

With this option you can delete all elements except for the elements with numbers *element\_0*, *element\_1*, etc. This enables you to clearly view some specific elements and nodes in a plot.

### 6.203 control\_mesh\_keep\_element\_group *index element\_group\_0 element\_group\_1 ...*

With this option you can delete all elements except for the elements with group numbers *element\_group\_0*, *element\_group\_1*, etc. This enables you to clearly view some specific elements and nodes in a plot.

### 6.204 **control\_mesh\_keep\_geometry** *index geometry\_item\_name geometry\_item\_index*

With this option you can delete all elements except for the elements present in the specified geometry. This enables you to clearly view some specific elements and nodes in a plot.

### 6.205 **control\_mesh\_keep\_node** *index node\_0 node\_1 ...*

With this option you can delete all nodes except for the nodes with numbers *node\_0*, *node\_1*, etc. This enables you to clearly view some specific elements and nodes in a plot.

### 6.206 **control\_mesh\_macro** *index macro\_item element\_group n ...*

With this record and the **control\_mesh\_macro\_parameters** record you define a macro region. The macro region will automatically be divided into finite elements.

The type of macro region is defined by *macro\_item*. You can set *macro\_item* to a **-sphere** (3D), **-cylinder** (3D), **-cylinder\_hollow** (3D), **-brick** (3D), **-rectangle** (2D/3D), **-circle** (2D), **-circle\_hollow** (2D), **-truss** (1D/2D/3D), **-truss\_beam** (1D/2D/3D) and **-bar** (1D).

The elements to be generated will get **element\_group** *element\_group*.

With *n ...* you define how much nodes and elements will be generated. For a **-cylinder**, you need to specify the number of nodes in the length direction, the number of nodes in radial direction and the number of nodes in circ. direction (there is always only one element in radial direction). For a **-cylinder\_hollow**, you need to specify the number of nodes in the length direction, the number of nodes over the wall thickness and the number of nodes in circ. direction. For a **-brick**, you need to specify the number of nodes in x-direction, the number of nodes in y-direction and the number of nodes in z-direction. For a **-circle** and **-sphere**, you need to specify 'fineness' of the mesh, which is a number 0, 1, 2, 3, ...; a higher number gives a higher fineness; typically use 3 or so. For a **-circle\_hollow**, you need to specify the number of nodes over the wall thickness, the number of elements in tangential direction. For a **-rectangle**, you need to specify the number of nodes in first direction and the number of nodes in second direction. For a **-bar**, you need to specify the number of nodes. For a **-truss**, you need to specify the number of nodes. For a **-truss\_beam**, you need to specify the number of nodes.

In the following example a sphere is generated

```
...
number_of_space_dimension 2
```

```

...
end_initia
...
control_mesh_macro 20 -sphere ...
control_mesh_macro_parameters 20 ...
...

```

#### 6.207 control\_mesh\_macro\_concentrate *index* ...

For the **-rectangle** macro you can specify with this **control\_mesh\_macro\_concentrate** record a mesh fineness concentration factor in the first direction and in the second direction. In each direction give a mesh fineness factor at the beginning and at the end (so two factors per direction). A smaller factor means smaller elements. The relative size of the factor determines where elements are concentrated, at the start or at the end.

#### 6.208 control\_mesh\_macro\_element *index element\_type*

With this option you can set the element type which will be generated with **control\_mesh\_macro** (with the same index). This option is only available in 2d and 3d.

For **element** you can use **-tria3**, **-tria6**, **-quad4** and **-quad9** in 2d. For **element** you can use **-tet4**, **-tet10**, **-hex8** and **-hex27** in 2d.

If this record is not specified then **-bar2** (1d), **-quad4** (2d) or **-hex8** (3d) will be generated.

Attention: in case you choose a quadratic element the macro geometry may not be exactly followed. In this case, leave the default linear elements, and use a global mesh refinement to quadratic elements afterwards, including the geometry to follow.

#### 6.209 control\_mesh\_macro\_parameters *index x y ...*

With this record you can specify the dimensions of the **control\_mesh\_macro** region.

For a **-sphere**, you need to specify the x, y, z coordinates of the middle of the sphere and the radius of the sphere. For a **-cylinder**, you need to specify the x, y, z coordinates at the start of the cylinder, the x, y, z coordinates at the end of the cylinder, the radius, the start angle and the end angle in degrees (which allows for an open section). For a **-cylinder\_hollow**, you need to specify the x, y, z coordinates at the start of the cylinder, the x, y, z coordinates at the end of the cylinder, the middle radius, the wall thickness, the start angle and the end angle in degrees (which allows for an open section). For a **-brick**, you need to specify the x, y, z coordinates at the middle, the length in x-direction, the length in y-direction, and the length in z-direction. For a **-circle**, you need to specify the x, y coordinates of the middle and also the radius. For a **-circle\_hollow**, you need to specify the same as for the **circle**

and additionally the wall thickness, the start angle and the end angle in degrees (which allows for an open section). For a **-rectangle**, you need to specify the x, y coordinates of the middle, the width and the height respectively. For a **-bar**, you need to specify the x coordinate of the middle and the length respectively. For a **-truss**, you need to specify the coordinates of the start and of the end respectively.

### 6.210 **control\_mesh\_map** *index switch*

A typical piece of input file is

```
...
global_element_dof_apply -no
...
... (input file with quadratic elements -hex20 or -hex27 or -tet10 or -prism15)
...
control_mesh_map ...-yes (map to linear elements -hex8 or -prism6 or -
tet4)
...
control_timestep ... (calculate with linear elements)
control_solver ...-matrix_pardiso (with pardiso solver)
...
control_mesh_map -yes (map back to quadratic elements)
...
control_timestep ... (calculate with quadratic elements)
control_solver ...-matrix_iterative_bicg (with bicg solver)
...
```

In this way, the last calculation with the quadratic elements gets as first guess for the bicg solver the solution field of the linear elements with the pardiso solver. This saves much computing time for bicg, especially in very large calculations. This strategy normally should only be used for large linear calculations. For this option always set **global\_element\_dof\_apply** **-no**.

### 6.211 **control\_mesh\_merge** *index switch*

If *switch* is set to **-yes**, then nodes with the same coordinates are merged into one node.

### 6.212 **control\_mesh\_merge\_eps\_coord** *index epsilon*

Distance below which nodes will be merged. Default some small value.

### 6.213 **control\_mesh\_merge\_macro\_generate** *index macro\_0 ...*

This record works together with the **control\_mesh\_merge** record.

With *macro\_0* etc. you can specify the indices of **control\_mesh\_macro\_\*** or **control\_mesh\_generate\_\*** records. Then the merging will only be done for nodes coming from the mesh generated by the macro or generate records with the specified indices.

### 6.214 **control\_mesh\_merge\_geometry** *index geometry\_entity\_item geometry\_entity\_index*

The mesh merging from **control\_mesh\_merge**, with the same index, will only be used for nodes in the geometry specified by *geometry\_entity\_item geometry\_entity\_index*.

### 6.215 **control\_mesh\_merge\_geometry\_not** *index geometry\_entity\_item geometry\_entity\_index*

The mesh merging from **control\_mesh\_merge**, with the same index, will not be used for nodes in the geometry specified by *geometry\_entity\_item geometry\_entity\_index*.

### 6.216 **control\_mesh\_mirror** *index axis*

This option mirrors the mesh. Thus you get twice as much elements and nodes. The *axis* should either be set to **-x**, **-y** or **-z**.

### 6.217 **control\_mesh\_move** *index move\_x\_constant move\_x\_linear\_x move\_x\_linear\_y move\_x\_linear\_z move\_y\_constant move\_y\_linear\_x move\_y\_linear\_y move\_y\_linear\_z move\_z\_constant move\_z\_linear\_x move\_z\_linear\_y move\_z\_linear\_z*

This option moves the mesh. Thus you get the same amount of elements and nodes, but just moved in space.

In the x-direction a node is moved over *move\_x\_constant* + *move\_x\_linear\_x* \* x + *move\_x\_linear\_y* \* y + *move\_x\_linear\_z* \* z.

Specify only data for the number of space dimensions.

### 6.218 **control\_mesh\_multiply** *index number\_of\_multiplications*

The mesh is multiplied *number\_of\_multiplications* times. In each multiplication the mesh gets double the amount of elements, because for each element a new element is generated with the same nodes.

### 6.219 **control\_mesh\_refine\_globally** *index refinement\_type*

This record activates global mesh refinement or global mesh coarsening. This is not available for **-tria3** and **-tet4** elements. Either *refinement\_method* is **-h\_refinement** (more of the same elements) or *refinement\_method* is **-p\_refinement** (higher order elements).

As a special option for the **-h\_refinement** method, the format **refine\_globally index -h\_refinement switch\_ξ switch\_η switch\_ζ** can be used. For example in 1D, only **refine\_globally index -h\_refinement switch\_ξ** should be specified. For example in the **-hex8** element,  $\xi$  is the isoparametric coordinate running from the first node to the second node,  $\eta$  runs from the first node the third node and  $\zeta$  runs from the first node to the fifth node. A isoparametric direction will be refined if the corresponding switch is set to **-yes**. This option allows for refinement in specific directions. It should be used with care however, and only gives proper results if the  $\xi, \eta$  and  $\zeta$  directions of the elements match.

The **control\_mesh\_refine\_globally** will automatically merge nodes which have the same position in space.

Rules for old and new:

- A new generated element inherits its data items from the old element it is generated from.
- If a new generated node is placed on an old element edge it inherits those data items of the old nodes on that old edge that have a property in common; then arbitrarily the data item of one of the old nodes is taken.
- If a new generated node is placed inside an old element it inherits those data items of the old nodes of that old element that have a property in common; then arbitrarily the data item of one of the old nodes is taken.
- For all new nodes the **node\_dof** records are interpolated from the old element nodes **node\_dof** records by using the old element interpolation functions.

See also **control\_mesh\_refine\_globally\_geometry**.

### 6.220 **control\_mesh\_refine\_globally\_geometry** *index geometry\_entity\_item geometry\_entity\_index*

This record can be used together with the **control\_mesh\_refine\_globally** record with the same index. If all nodes of an element edge is part of the geometrical entity, the new generated nodes are also placed on that geometrical entity. This typically is used to follow curved edges of the domain.

The **control\_mesh\_refine\_locally** will automatically merge nodes which have the same position in space.

### 6.221 **control\_mesh\_refine\_locally** *index percentage*

An elements will be refined depending on the size of a solution variable. The solution variable can be chosen via **control\_mesh\_refine\_locally\_dof**.

The percentage of elements which will be refined is specified by *percentage*. Typically *percentage* is 10 or so.

This local mesh refinement is only available for **-bar2**, **-bar3**, **-tria3**, **-tria6**, **-tet4** and **-tet10** elements; there should be no other elements in the mesh.

See the rules for old and new at **control\_mesh\_refine\_globally**.

### 6.222 **control\_mesh\_refine\_locally\_dof** *index dof*

With *dof* you can set which dof will be used for deciding if an element should be refined. The size of the doffield will be used.

Possibilities for *dof* are: **-materi\_damage**, **-materi\_displacement**, **-materi\_plasti\_kappa**, **-materi\_plasti\_kappa\_shear**, **-materi\_strain\_elasti**, **-materi\_strain\_plasti**, **-materi\_strain\_total**, **-materi\_stress**, **-materi\_velocity**, **-materi\_void\_fraction** and

As a special option you can set *dof* to **-nothing**; then an element is refined always.

For finding localization zones (e.g. shear bands) choosing **-materi\_strain\_plasti** or **-materi\_damage** seems to be most robust.

See also **control\_mesh\_refine\_locally\_geometry**.

**6.223** `control_mesh_refine_locally_geometry` *index geometry\_entity\_item geometry\_entity\_index*

This record can be used together with the `control_mesh_refine_locally` record with the same index. If all nodes of an element edge is part of the geometrical entity, the new generated nodes are also placed on that geometrical entity. This typically is used to follow curved edges of the domain.

**6.224** `control_mesh_refine_locally_minimal_size` *index minimal\_size*

Element with minimal size below the specified *minimal\_size* will not be refined. The minimal element size is defined as the largest node distance between nodes of the element. Default the minimal allowed size is 0.

**6.225** `control_mesh_refine_locally_not` *index geometry\_entity\_0 geometry\_entity\_index\_0*

The refinement as specified in the `control_mesh_refine_locally` record with the same index, will not be applied on the geometry specified by *geometry\_entity\_0 geometry\_entity\_index\_0*.

**6.226** `control_mesh_refine_locally_not_method` *index method*

Set *method* to **-all** or **-any**. If *method* is set to **-all**, then the corresponding `control_mesh_refine_locally_not` is applied to elements for which all nodes are inside the specified geometry. If *method* is set to **-any**, then the corresponding `control_mesh_refine_locally_not` is applied to elements for which any of the nodes is inside the specified geometry. Default *method* is **-all**.

**6.227** `control_mesh_refine_locally_only` *index geometry\_entity\_0 geometry\_entity\_index\_0*

The refinement as specified in the `control_mesh_refine_locally` record with the same index, will only be applied on the geometry specified by *geometry\_entity\_0 geometry\_entity\_index\_0*.

**6.228** `control_mesh_refine_locally_only_method` *index method*

Set *method* to **-all** or **-any**. If *method* is set to **-all**, then the corresponding `control_mesh_refine_locally_only` is applied to elements for which all nodes are inside the specified geometry. If *method* is set to **-any**, then the corresponding `control_mesh_refine_locally_only` is applied to elements for which any of the nodes is inside the specified geometry. Default *method* is **-all**.

**6.229 control\_mesh\_remove** *index method element\_group\_0 element\_group\_1 element\_group\_2 ...*

With *method* set to **-method1** you can remove elements of *element\_group\_0* if they are completely located inside a elements of groups *element\_group\_1*, *element\_group\_2* etc.

With *method* set to **-method3** you can remove elements if all nodes of these elements have an mpc (that is, **node\_mpc** exists for all nodes of an element). Thus for *method* set to **-method3** you do not need to specify *element\_group\_0*, *element\_group\_1*, *element\_group\_2* etc.

**6.230 control\_mesh\_remove\_geometry** *index geometry\_item\_name geometry\_item\_index*

With this record you can restrict to which geometry the **control\_mesh\_remove** will be applied.

**6.231 control\_mesh\_remove\_keep\_geometry** *index geometry\_item\_name geometry\_item\_index*

If elements are being removed once with the **control\_mesh\_remove** command, they keep on being removed in the future if they are part of the geometry as specified in this **control\_mesh\_remove\_keep\_geometry** command.

**6.232 control\_mesh\_remove\_really** *index switch*

If *switch* is set to **-yes** elements removed by the **control\_mesh\_remove** command are really removed. If *switch* is set to **-no** elements removed by the **control\_mesh\_remove** command are not really removed; they are made inactive instead, and will become active again at the moment that they are no longer being removed by the **control\_mesh\_remove** command.

**6.233 control\_mesh\_remove\_really\_activate\_all** *index switch*

See **control\_mesh\_remove\_really\_activate\_factor**.

**6.234 control\_mesh\_remove\_really\_activate\_factor** *index factor*

When an element becomes active again, after being removed before, we need to decide what the stresses and pore pressures are in nodes of the activated element.

For nodes of the element which were connected to already active elements nothing extra is done.

For nodes of the element which were not connected to already active elements, the average value of the stresses and pore pressures from already active nodes (connected to already active elements) are taken. However, with this *factor*, you can specify to which part the stresses and pore pressures of already nodes will actually be used. Set *factor* to 0 if you want to reactivate the nodal stresses and pore pressures with 0. Set *factor* to 1 if you want to reactivate the nodal stresses and pore pressures completely with the stresses and pore pressures from already active neighbour nodes. Or set a *factor* between 0 and 1 if you do something in between.

As an extra option you can set the *switch* in **control\_mesh\_remove\_really\_activate\_all** to **-yes**. Then the stresses and pore pressures in ALL nodes of the activated element will be reactivated using the *factor* (so not only the nodes which were not active before).

Default, if **control\_mesh\_remove\_really\_activate\_factor** is not specified, the *factor* is set to 1.

#### 6.235 **control\_mesh\_renumber** *index lowest\_element lowest\_node*

The element numbers are made strictly sequential starting from *lowest\_element* and the node numbers are made strictly sequential starting from *lowest\_node*. Beware using **control\_renumber** in combination with, for example, node numbers in printing of **node\_dof** records; use **post\_point** records instead.

#### 6.236 **control\_mesh\_renumber\_element\_geometry\_offset** *index offset*

While renumbering elements the element geometry number will be offset with *offset*.

#### 6.237 **control\_mesh\_renumber\_element\_group\_offset** *index offset*

While renumbering elements the element group number will be offset with *offset*.

#### 6.238 **control\_mesh\_rotate** *index n*

After rotation *n* is the number of elements in rotational direction for a rotation over 360 degrees. After rotation the old *y* direction becomes the new *z* direction. The following data is transferred in the rotation process: **element**, **element\_group**, **node** and **node\_dof**. A 2D **-tria3** element becomes a 3D **-prism6** element and a 2D **-quad4** element becomes

a 3D **-hex8** element; other 2D elements can presently not be rotated. All data that is not valid in 3D, like for example a 2D line etc, will be deleted in the rotation process.

This **control\_mesh\_rotate** is convenient when the first part of calculation is axisymmetric, for example loading a pile vertically in a soil, and the second part of the calculation is 3D, for example loading the top of the pile in some horizontal direction. Then first an axi-symmetric calculation can be performed, and the results can be used to start a 3D calculation.

If a **-quad4** elements has a side on the y-axis in the 2D mesh, the element is rotated to a **-prism6** element; the **-quad4** element should have the side with local node numbers 0 and 1 on the y-axis, which is the case if you generated the elements with a **control\_mesh\_macro**. You should not use other elements with a side on the y-axis when rotating the mesh.

This **control\_mesh\_rotate** deletes all data, except **element**, **element\_group**, **node**, **node\_dof**, **element\_interface\_strain** and **element\_interface\_stress** will be rotated to 3D. Furthermore, **control\_input** will be available afterwards, so that all 3d data can be set in an extra input file, which is read after the mesh rotation.

If you use any history variables in the model, these should be scalars (and thus not vectors or matrices); otherwise rotation will not go ok for the history variables.

### 6.239 control\_mesh\_rotate\_angle *index angle*

With *angle* you can specify an angle in degrees up to which the mesh rotation should be done for the **control\_mesh\_rotate** with the same index. Typically you could use 90 degrees or 180 degrees for *angle*. Default, if this **control\_mesh\_rotate\_angle** is not specified, *angle* will be set to 360.

### 6.240 control\_mesh\_split *index switch*

If *switch* is set to **-yes** then each **-quad4** element is split into four **-tria3** elements and each **-hex8** element is split into twelve **-tet4** elements. Further, each **-quad9** element is split into four **-tria6** elements and each **-hex27** element is split into six **-tet10** elements. Further, each **-tria6** element is split into four **-tria3** elements.

See the rules for old and new at **control\_mesh\_refine\_globally**. See also **control\_mesh\_split\_element\_to** and **control\_mesh\_split\_only**.

Splitting a 3D mesh will only work correctly on certain regular grids; you need to check the splitted mesh.

#### 6.241 **control\_mesh\_split\_element\_from** *index name*

Split only elements with the specified *name*.

#### 6.242 **control\_mesh\_split\_element\_to** *index name*

If you are splitting **-hex8** elements, then you can set **name** either to **-tet4** or **-prism6**. Default, if **control\_mesh\_split\_element\_to** is not specified, **-tet4** is used.

If you are splitting **-hex27** elements, then you can set **name** either to **-tet10** or **-prism18**. Default, if **control\_mesh\_split\_element\_to** is not specified, **-tet10** is used.

#### 6.243 **control\_mesh\_split\_only** *index geometry\_entity geometry\_entity\_index*

If this record is used, the corresponding **control\_mesh\_split** record will only be applied on elements which have at least one node on the geometry specified by *index geometry\_entity\_name geometry\_entity\_index*.

#### 6.244 **control\_mesh\_switch\_index** *dir0 dir1*

With this option you can switch x, y and z values for all nodal coordinates. Each of *dir0* and *dir1* can be set to either **-x**, **-y** or **-z**. Then the specified coordinates *dir0* and *dir1* will be switched for all nodes.

#### 6.245 **control\_mesh\_truss\_distribute\_mpc** *index switch*

If *switch* is set to **-yes** the nodes of truss elements are fixed with multi point constraints (mpc's) to the isoparametric elements through which the trusses run. This typically can be used for modeling reinforcement bars in a concrete embedment, where the bars follow the displacements (and temperatures if present) of the concrete.

If **control\_mesh\_truss\_distribute\_mpc\_exact** *switch* is set to **-yes**, truss elements are redistributed (that is, more small truss elements will be made), in such way that each truss gets a node when it enters an isoparametric element or ends internally in an isoparametric element. This **control\_mesh\_truss\_distribute\_mpc\_exact** comes handy when you initially have large trusses relative to the isoparametric elements.

Truss below a minimum length as specified in **control\_mesh\_truss\_distribute\_mpc\_exact\_minimal\_length** will not be generated; default the minimal length *tolerance* is set to some small value. With **control\_mesh\_truss\_distribute\_mpc\_exact\_minimal\_length\_connect** you can determine if the generated trusses jumping a space below the minimal length will be connected or will be not-connected (loose); set the *switch* to **-yes** if you want the truss to be

connected in such case. Please realise that the connection is ensured only for the trusses generated from 1 old truss; connection is not ensured for trusses generated from different old truss elements.

This **control\_mesh\_truss\_distribute\_mpc** option is done for truss groups as specified in **control\_mesh\_truss\_distribute\_mpc\_element\_group\_truss** or in **control\_mesh\_truss\_distribute\_mpc\_geometry\_truss**. Only one of **control\_mesh\_truss\_distribute\_mpc\_element\_group\_truss** and **control\_mesh\_truss\_distribute\_mpc\_geometry\_truss** can be specified. If none of **control\_mesh\_truss\_distribute\_mpc\_element\_group\_truss** and **control\_mesh\_truss\_distribute\_mpc\_geometry\_truss** is specified the distribution will be done for all trusses.

Default Tochnog will look for all isoparametric elements how to distribute the trusses. To save computer time you can restrict the geometry or element group of the isoparametric elements where Tochnog will look with **control\_mesh\_truss\_distribute\_mpc\_element\_group\_isoparametric** and **control\_mesh\_truss\_distribute\_mpc\_geometry\_isoparametric**.

Please notice that if you are using geometries in **control\_mesh\_truss\_distribute\_mpc\_geometry\_truss** or **control\_mesh\_truss\_distribute\_mpc\_geometry\_isoparametric** these can in fact be a **geometry\_set**.

In case you specify both of the above **\*\_truss** and **\*\_isoparametric**, the number of specified values (groups or geometries) should be the same. Then the first value specified for the truss will be combined with the first value specified for the isoparametric elements, the second value specified for the truss will be combined with the second value specified for the isoparametric elements, etc. For example, if you specify two groups for **control\_mesh\_truss\_distribute\_mpc\_element\_group\_truss** and two groups for **control\_mesh\_truss\_distribute\_mpc\_element\_group\_isoparametric** the first specified truss group will be distributed over the first specified isoparametric group, and the second specified truss group will be distributed over the first specified isoparametric group.

If *switch* in **control\_mesh\_truss\_distribute\_mpc\_air** is set to **-yes**, trusses will also be generated in the center of the truss is not inside an isoparametric element. If *switch* in **control\_mesh\_truss\_distribute\_mpc\_air** is set to **-no**, trusses will not be generated in the center of the truss is not inside an isoparametric element. Default *switch* is **-yes**.

A typical input file looks like:

```
control_mesh_truss_distribute_mpc 10 -yes
control_mesh_truss_distribute_mpc_exact 10 -yes
control_mesh_truss_distribute_mpc_geometry 10 -element_geometry
123
```

Only one **control\_mesh\_truss\_distribute\_mpc** record is allowed in the input file. As a special option you can also generate **truss\_beam** elements in stead of **truss** elements.

**6.246 control\_mesh\_truss\_distribute\_mpc\_air** *index switch*

See **control\_mesh\_truss\_distribute\_mpc**.

**6.247 control\_mesh\_truss\_distribute\_mpc\_dof** *dof\_0 dof\_1 ...*

The *dof\_0 dof\_1 ...* specify the dof's that should be set equal, e.g. **-velx**, **-vely** etc.

**6.248 control\_mesh\_truss\_distribute\_mpc\_element\_group\_truss**  
*index element\_group\_0 element\_group\_1 ...*

See **control\_mesh\_truss\_distribute\_mpc**.

**6.249 control\_mesh\_truss\_distribute\_mpc\_element\_group\_isoparametric**  
*index element\_group\_0 element\_group\_1 ...*

See **control\_mesh\_truss\_distribute\_mpc**.

**6.250 control\_mesh\_truss\_distribute\_mpc\_exact** *index switch*

See **control\_mesh\_truss\_distribute\_mpc**.

**6.251 control\_mesh\_truss\_distribute\_mpc\_exact\_minimal\_length**  
*index tolerance*

See **control\_mesh\_truss\_distribute\_mpc**.

**6.252 control\_mesh\_truss\_distribute\_mpc\_exact\_minimal\_length\_connect**  
*index switch*

See **control\_mesh\_truss\_distribute\_mpc**.

**6.253 control\_mesh\_truss\_distribute\_mpc\_geometry\_truss** *index geometry\_entity\_name\_0 geometry\_entity\_index\_0 geometry\_entity\_name\_1 geometry\_entity\_index\_1 ...*

See **control\_mesh\_truss\_distribute\_mpc**.

**6.254 control\_mesh\_truss\_distribute\_mpc\_geometry\_isoparametric** *index geometry\_entity\_name\_0 geometry\_entity\_index\_0 geometry\_entity\_name\_1 geometry\_entity\_index\_1 ...*

See **control\_mesh\_truss\_distribute\_mpc**.

**6.255 control\_mpc\_apply** *index switch*

If *switch* is set to **-yes** then mpc conditions will be used for the control index. If *switch* is set to **-no** then mpc conditions will not be used for the control index. Default, if **control\_mpc\_apply** is not specified, *switch* is set to **-yes**.

**6.256 control\_mpc\_element\_group** *index switch*

If *switch* is set to **-yes** the **mpc\_element\_group** records will be evaluated at all timesteps for the current control index. If *switch* is set to **-no** the **mpc\_element\_group** records will only be evaluated when the mesh has been changed. This option can only be used if there are only mpc's coming from this option, and not from other mpc data.

Default, if **control\_mpc\_element\_group** is not specified, the *switch* is set to **-no**.

**6.257 control\_plasti\_apply** *index switch*

If *switch* is set to **-no**, any plasticity data in the input file will be ignored. This is done for timestep records with the same index.

This option is convenient for testing your input file just linear, without the need to outcomment each and every part with plasticity data. See also **plasti\_apply**.

**6.258 control\_post** *index switch*

If *switch* is set to **-yes** all post processing commands are evaluated for index *index*. This enforces evaluation of post processing command even if no timesteps are performed or so.

### 6.259 **control\_post\_apply** *index switch*

Setting *switch* to **-no** prevents post processing commands to be evaluated for control commands with the same index. Postprocessing commands have **post** in the name (only the **post\_node\_rhside\_ratio** will be evaluated always, independent of **control\_post\_apply**).

### 6.260 **control\_post\_element\_force** *index switch*

You can save CPU time in timesteps with the same index by setting *switch* to **-no**, which prevents **post\_element\_force** commands to be evaluated in timesteps with the same index.

### 6.261 **control\_print** *index data\_item\_name\_0 data\_item\_name\_1 ...*

This is the normal printing command. A **control\_print** record causes the data items with name *data\_item\_name\_0*, etc. to be printed. Example

```
control_print 1 -node -node_dof
```

See also: **print\_filter**.

### 6.262 **control\_print\_beam\_force\_moment** *index switch*

This option prints the beam forces and moments through a set of beams starting at place  $x_{start}$ ,  $y_{start}$ ,  $z_{start}$  and ending at  $x_{end}$ ,  $y_{end}$ ,  $z_{end}$  as specified in **control\_print\_beam\_force\_moment\_coordinates**. In 2D only  $x$  and  $y$  coordinates need to be specified. The forces and moments are printed in the file `beam_force_moment.index`. In fact, if the element contains a truss (either a truss element or a truss-beam element), the truss force will be used for the axial force. The first column in the file is the distance from the start point. The following columns contain in the local beam axes `force_x_first_node` `force_y_first_node` `force_z_first_node` `moment_x_first_node` `moment_y_first_node` `moment_z_first_node` `force_x_second_node` `force_y_second_node` `force_z_second_node` `moment_x_second_node` `moment_y_second_node` `moment_z_second_node`. The *switch* needs to be set to **-separate\_index** or **-separate\_sequential**. See also **control\_print\_beam\_force\_moment\_switch**.

### 6.263 **control\_print\_beam\_force\_moment\_coordinates** *index x\_start y\_start z\_start x\_end y\_end z\_end*

See **control\_print\_beam\_force\_moment**.

### 6.264 **control\_print\_beam\_force\_moment\_switch** *index switch*

If you set *switch* to **-yes**, the definition of the beam forces and moments is changed (multiplied with a -1). So you can get exactly the definition that you want.

### 6.265 **control\_print\_database** *index switch*

If *switch* is set to **-separate\_index**, the complete database is be printed. See the example below

```
control_print_database 6 -separate_index
```

This database contains the complete status of the calculation. For example if *index* is 6, the data base is printed in the file `input_file_name6.dbs`. As a special option, you can print databases with sequential numbers by setting *switch* to **-separate\_sequential**.

If tochnog exists with an error, for example due to non-convergence, a complete database is printed in **input\_file\_name\_error.dbs**. Otherwise, a complete database will be printed at the end of the calculation.

### 6.266 **control\_print\_database\_method** *index method*

If *method* is set to **-all** then all database base records will be printed in the database. If *method* is set to **-size\_tot** then the size of all database base records will be printed in the database. If *method* is set to **-size\_tot\_large** then the size of database base records larger than 1 Mb will be printed in the database.

When using **-size\_tot** or **-size\_tot\_large** also the size of the system matrix is printed in the database.

Default, if **control\_print\_database\_method** is not specified, the *method* is set to **-all**.

### 6.267 **control\_print\_data\_versus\_data** *index data\_item\_name\_0 index\_0 number\_0 data\_item\_name\_1 index\_1 number\_1 ...*

This option prints columns of data for each time step. Print in the first column the *number\_0* value of *data\_item\_name\_0* with index *index\_0*. Similar in the second column for *data\_item\_name\_1 index\_1 number\_1*. Etc. (for all values). All results will be printed in the file `problemname.dvd`.

Typically, the data item names can be **-node\_\_dof** such that dof's can be printed against each other in time. If the data item names are **-node\_\_dof**, then *number\_0* and *number\_1*, etc. can be names of **dof\_label** (eg **-velx**).

Also typically, the data item names can be **-node\_\_dof\_\_calcul** such that post calculation results can be printed against each other in time. If the data item names are **-node\_\_dof\_\_calcul** or **post\_\_point\_\_dof\_\_calcul** or so, then *number\_0* and *number\_1*, etc. can be names of **post\_\_calcul\_\_label** (eg **-aept**).

Otherwise, for example, if *number\_0* is 3 then the fourth value of *data\_item\_name\_0* is printed.

Example:

```
control__print__data__versus__data 0 -node__dof 2 -temp
-node__dof 2 -sigxx -node__dof 2 -sigxx
```

Another example:

```
post__point 0 0.0 1.0
post__calcul -materi__stress -average -materi__stress -size__dev

control__print__data__versus__data 20
-time__current 0 0
-post__point__dof__calcul 0 0 -post__point__dof__calcul 0 1
```

In the last example, the **-post\_\_point\_\_dof\_\_calcul 0 0** stands for 'the **post\_\_point\_\_dof\_\_record** with index 0 and the 0'th number which is the first value so the average of the stresses'.

For data that is not present Tochnog will print a 0.

See also: **control\_\_print**.

**6.268 control\_\_print\_\_data\_\_versus\_\_data\_\_factor** *index factor\_0 factor\_1 ...*

Optionally specify a multiplication factor for each of the data item of **control\_\_print\_\_data\_\_versus\_\_data**. This can, by example, be convenient if you want to change to sign or so. If you specify this record, a factor should be given for each data item.

### 6.269 **control\_print\_dof** *index switch*

Results for the primary dof's will be printed, including also the coordinates at which the results hold. Also results for **node\_dof\_calcul** records will be printed. The printed files will contain lines like *x*, *y*, *z* and *dof* (where *dof* is the dof, e.g. **temp**). In 1D only *x* will be printed, etc.

As extra also the coordinates themselves are printed in files.

If *switch* is set to **-separate\_index** the filenames will be like *dof.index*.

If *switch* is set to **-separate\_sequential** then the filenames will be sequentially numbered, like *dof.0*, *dof.1*, etc.

### 6.270 **control\_print\_dof\_id** *index switch*

This record works in combination with the **control\_print\_dof** record. If *switch* is set to **-yes** also the node number ('identity') is written. So for example in 3D the file will contain lines with *x*, *y*, *z*, *dof* and node number.

Default, if **control\_print\_dof\_id** is not specified, *switch* is set to **-yes**.

### 6.271 **control\_print\_dof\_smooth\_dof** *index dof\_0 dof\_1 ...*

This option allows you to smooth results for **control\_print\_dof**. With *dof\_0 dof\_1 ...* you specify the dof's to be smoothed. As a special option you can specify **-all** so that all dof's will be smoothed.

The smoothing is done a number of times, with increasing smooth results. You can specify this number of times with the optional **control\_print\_dof\_smooth\_n**; if you don't specify this optional number of smoothings it is done 10 times.

### 6.272 **control\_print\_dof\_smooth\_n** *index number\_of\_smoothings*

See **control\_print\_dof\_smooth\_dof**.

### 6.273 **control\_print\_dof\_line** *index switch*

This **control\_print\_dof\_line** record together with the **control\_print\_dof\_line\_coordinates** and **control\_print\_dof\_line\_n** records print values of the **node\_dof** records and **node\_dof\_calcul** records along a line in space to files.

The start point of the first line segment is given by  $x\_0\ y\_0\ z\_0$ , and the end point of the first line segment is given by  $x\_1\ y\_1\ z\_1$ , the start point of the second line segment is given by  $x\_1\ y\_1\ z\_1$ , and the end point of the second line segment is given by  $x\_2\ y\_2\ z\_2$ , etc.

In 1D only the x-coordinates of the start point and end point need to be specified, etc. The parameter  $n$  determines how many points will be printed along the line.

The printed files will contain lines like  $x$ ,  $y$ ,  $z$  and  $dof$  (where  $dof$  is the dof, e.g. **temp**). In 1D only  $x$  will be printed, etc.

If *switch* is set to **-separate\_index** the filenames will be like *dof.index*.

If *switch* is set to **-separate\_sequential** then the filenames will be sequentially numbered, like *dof.0*, *dof.1*, etc.

In **control\_print\_dof\_line\_method** you can set *node\_type* either to **-node** or **-node\_start\_refined**. Then the coordinates in the printed file will contain either the values of **node** or the values of **node\_start\_refined**. In case you use an updated lagrange formulation where the mesh nodes follow the material the values of **node** and **node\_start\_refined** will differ; in case you do a geometrically linear analysis the values will not differ. Default *node\_type* is set to **-node\_start\_refined**.

With **control\_print\_dof\_line\_element\_group** you can set a specific element groups for which the printing should be done.

With **control\_print\_dof\_line\_eps\_iso** you set the tolerance with which a point of the specified line is accepted to be part of an element. The default value is 1.e-3. You can increase the default value if the mesh is not exactly adjusted to the line.

**6.274 control\_print\_dof\_line\_coordinates** *index x\_0 y\_0 z\_0 x\_1 y\_1 z\_1 x\_2 y\_2 z\_2 ...*

See **control\_print\_dof\_line**.

**6.275 control\_print\_dof\_line\_element\_group** *index element\_group\_0 element\_group\_1 ...*

See **control\_print\_dof\_line**.

**6.276 control\_print\_dof\_line\_eps\_iso** *index eps\_iso*

See **control\_print\_dof\_line**.

### 6.277 **control\_print\_dof\_line\_method** *index node\_type*

See **control\_print\_dof\_line**.

### 6.278 **control\_print\_dof\_line\_move** *index switch*

If *switch* is set to **-yes** the **control\_print\_dof\_line\_coordinates** with the same index will be moved along with the velocity field. Thus, with this option you can follow with a **control\_print\_dof\_line** the dof's of material particles.

Please realise that this option should only be used if **materi\_velocity** is initialised in the initialisation part.

### 6.279 **control\_print\_dof\_line\_n** *index n*

See **control\_print\_dof\_line**.

### 6.280 **control\_print\_dof\_line\_time** *index switch*

If *switch* is set to **-yes** the first line of each file will specify the **time\_current** at which the file is written (in gnuplot comment format).

### 6.281 **control\_print\_dof\_point** *index switch*

This **control\_print\_dof\_point** record prints values of the **node\_dof** records and **node\_dof\_calcul** records in a point in space to files.

The point is given by  $x\ y\ z$ ,

In 1D only the x-coordinates of the start point and end point need to be specified, etc.

The printed files will contain lines like  $x, y, z$  and *dof* (where *dof* is the dof, e.g. **temp**). In 1D only  $x$  will be printed, etc.

If *switch* is set to **-separate\_index** the filenames will be like *dof.index*.

If *switch* is set to **-separate\_sequential** then the filenames will be sequentially numbered, like *dof.0*, *dof.1*, etc.

### 6.282 `control_print_dof_point_coordinates` *index x y z*

See `control_print_dof_line`.

### 6.283 `control_print_dof_point_time` *index switch*

If *switch* is set to **-yes** the first line of each file will specify the **time\_current** at which the file is written (in gnuplot comment format).

### 6.284 `control_print_dof_rhside` *index switch*

If *switch* is set to **-yes** then results for right-hand-side for the primary dof's will be printed, including also the coordinates at which the results hold.

For example, for the file `temp_rhside.index` will contain lines containing *x*, *y*, *z* and right-hand-side of **-temp** (that is, heat flux). In 1D only *x* will be printed, etc.

### 6.285 `control_print_element` *index data\_item\_name*

With this option you can print values from element data versus coordinates. Select either **-element\_truss\_force** or **-element\_beam\_force\_moment** for *data\_item\_name*.

The normal truss forces of the **-element\_truss\_force** records will be printed in the file **element\_truss\_force\_n.index**. This file will contain lines containing *x*, *y*, *z* and normal truss force. In 1D only *x* will be printed, etc.

The lateral beam shear forces of the **-element\_beam\_force\_moment** records will be printed in the file **element\_beam\_force\_moment\_q.index**. This file will contain lines containing *x*, *y*, *z* and lateral beam shear force. In 1D only *x* will be printed, etc. The shear force will always be calculated as an absolute value.

The beam moments of the **-element\_beam\_force\_moment** records will be printed in the file **element\_beam\_force\_moment\_m.index**. This file will contain lines containing *x*, *y*, *z* and beam moment. In 1D only *x* will be printed, etc.

How the data is printed depends on how *method* is set in **control\_print\_element\_method**. If *method* is set to **-middle** then only the average value of the element data and the coordinate of the middle of the element is printed for each element. If *method* is set to **-node** then the two nodal values and nodal coordinates are printed for each element.

### 6.286 **control\_print\_element\_method** *index method*

Set *method* to **-middle** or **-node**. If **control\_print\_element\_method** is not specified then **-middle** is used. See also **control\_print\_element**.

### 6.287 **control\_print\_filter** *index print\_filter\_index\_0 print\_filter\_index\_1 ...*

See **print\_filter**.

### 6.288 **control\_print\_frd** *index switch*

Activate printing of results in Calculix output format **frd**. Only results for 2D and 3D isoparametric elements are printed presently. For structural elements (trusses, beams, ...) nothing is printed.

For example if the input file name is **excavation.dat** and *index* is 100 and *switch* is set to **-separate\_index** then results are printed in the file is **excavation\_100.frd**.

For example if the input file name is **excavation.dat** and *switch* is set to **-separate\_sequential** then results are printed in the files is **excavation\_0.frd**, **excavation1.frd**, etc.

For example if the input file name is **excavation.dat** and *switch* is set to **-yes\_sequential** then results are printed in the files is **excavation.frd**.

The frd files can be plotted by the **prepomax** pre- and postprocessor, see [http://lace.fs.uni-mb.si/wordpress/borovinsek/?page\\_id=41](http://lace.fs.uni-mb.si/wordpress/borovinsek/?page_id=41). Since prepomax presently cannot plot 2d elements, Tochnog extrudes 2d calculations to a fictive thickness of 1 when printing the frd files.

You also can use the CGX postprocessor of calculix itself , see <http://www.bconverged.com/download.php>.

Since Freecad and Prepomax like specific names of results we write the following names:

- **DISP** for **materi\_displacement** or **materi\_velocity\_integrated**
- **STRESS** for **materi\_stress**
- **TOSTRAIN** for **materi\_strain\_total**
- **NDTEMP** for **condif\_temperature**
- **PEEQ** for **post\_calcul-groundflow\_pressure-total\_pressure** (if **print\_frd\_freecad** is **-yes**)

For other results the Tochnog names are used, up to the allowed 8 characters in frd files.

FreeCAD presently only reads frd files which contain displacements and stresses and total strains. Thus, if these are not initialised in your tochnog input file and if **print\_frd\_freecad** is **-yes** then tochnog will not write the frd file for freecad.

See also **control\_print\_frd\_prepomax**.

#### 6.289 **control\_print\_frd\_freecad** *index switch*

If *switch* is set to **-yes** the frd files are written specifically suited for the **freecad** program. This is done for the **control\_print\_frd** command with the same index. If *switch* is set to **-no** the frd files are not written specifically suited for the **freecad** program. See also **print\_frd\_freecad**.

#### 6.290 **control\_print\_frd\_prepomax** *index switch*

If *switch* is set to **-yes** the frd files are written specifically suited for the **prepomax** program. This is done for the **control\_print\_frd** command with the same index. If *switch* is set to **-no** the frd files are not written specifically suited for the **prepomax** program. See also **print\_frd\_prepomax**.

#### 6.291 **control\_print\_frequency\_timeinterval** *index timeinterval*

This **control\_print\_frequency\_timeinterval** record causes **control\_print\_\*** other than **control\_print**, **control\_print\_history** and **control\_print\_data\_versus\_data** to be done each time after a time interval has passed, and always also at the end of the time increment. This **control\_print\_frequency\_timeinterval** record should only be used in combination with **control\_timestep** (with the same index). All **control\_print\_\*** printing will be influenced except **control\_print**, **control\_print\_history** and **control\_print\_data\_versus\_data** printing.

Example:

```
control_timestep 10 0.04 0.41
control_print_gid 10 -yes
control_print_frequency_timeinterval 10 0.15
```

In this example gid data is written at times 0.16, 0.32, 0.41

### 6.292 **control\_print\_frequency\_timestep** *index timestep*

This **control\_print\_frequency\_timestep** record causes **control\_print\_\*** other than **control\_print**, **control\_print\_history** and **control\_print\_data\_versus\_data** to be done each time after a number of time timesteps has passed, and always also at the end of the time increment. This **control\_print\_frequency\_interval** record should only be used in combination with **control\_timestep** (with the same index). All **control\_print\_\*** printing will be influenced except **control\_print**, **control\_print\_history** and **control\_print\_data\_versus\_data** printing.

Example:

```
control_timestep 10 0.04 0.41
control_print_gid 10 -yes
control_print_frequency_timestep 10 5
```

In this example gid data is written at times 0.20, 0.40, 0.41

### 6.293 **control\_print\_gid** *index switch*

Print the mesh and the dof's in a file which can be plotted with the GID pre-post processor if *switch* is set to **-yes**. For example, if the input file is called turbine.dat then the mesh is written in the turbine\_flavia.msh file. The results are written in the turbine\_flavia.res.

The mesh and results for dof's will always be written at the end of the calculation.

Since GID gets confused when the number of elements changes between several **control\_print\_gid** records, Tochnog will only print GID results for the last mesh used.

Coordinates for nodes will be written in the original configuration. If **materi\_velocity** is initialized, also a vector **mesh\_deform** will be written for GID which contains the deformation between the original mesh configuration and the deformed mesh configuration. Use the **deform mesh** menu in GID, to draw the deformed configuration by applying the vector **mesh\_deform** with a factor 1. If **materi\_displacement** is initialised the **mesh\_deform** contains the nodal displacements. If **materi\_velocity\_integrated** is initialised the **mesh\_deform** contains the integrated nodal velocities. Else **mesh\_deform** contains the current value of **node** minus the start value of the nodal coordinates.

For 2D interface elements which have strains and stresses, the normal stress **interface\_sign**, the tangential shear stress **interface\_sigt**, the normal strain **interface\_epsn** and the tangential shear strain **interface\_epst**, are written to the GID results file.

The following data is written also to the gid file and can serve as a help to check the validity of your input file. This data is only available after one or more time steps are taken.

- **condif\_bounda\_dof**, boundary conditions on temperature.
- **condif\_heat\_edge\_normal**, distributed prescribed heat flow on an edge.
- **condif\_convection\_edge\_normal**, distributed convection heat flow on an edge.
- **condif\_radiation\_edge\_normal**, distributed convection heat flow on an edge.
- **groundflow\_bounda\_dof**, boundary conditions on groundflow hydraulic pressure head.
- **materi\_bounda\_force**, discrete forces on nodes.
- **materi\_force\_edge**, distributed forces on nodes.
- **materi\_force\_edge\_normal**, distributed normal forces on nodes.
- **materi\_force\_edge\_projected**, distributed projected forces on nodes.
- **materi\_force\_edge\_water**, distributed water forces on nodes.
- **materi\_force\_volume**, distributed volume forces on nodes.
- **materi\_force\_gravity**, distributed gravity forces on nodes.
- **materi\_bounda\_dof**, boundary conditions on materi velocity on nodes.
- **materi\_support\_edge\_normal**, distributed support forces on nodes.
- **materi\_rhside\_free**, unbalance forces for **materi\_velocity** ( for free displacements) on nodex.
- **materi\_rhside\_fixed**, reaction forces for **materi\_velocity** ( for fixed displacements) on nodex.
- **element\_materi\_force\_edge**, norm of distributed forces on elements.
- **element\_materi\_force\_edge\_normal**, norm of distributed normal forces on an edge on elements.
- **element\_materi\_force\_edge\_water**, norm of distributed water forces on an edge on elements.
- **plasti\_reduction\_factor**, reduction factor for plasticity parameters from **group\_materi\_plasti\_eleme** etc.

If you have specified **print\_node\_geometry\_present** then the gid files will contain **geometry\_...** values which are 1 on nodes present in a geometry.

The **materi\_bounda\_dof** you can view in gid with **View results, Display vectors, materi bounda dof, All**. The other data you can view in GID for example with **View results, Display vectors, force edge normal, | force edge normal |** . Above with 'distributed' we mean that results are per unit area.

For isoparametric elements the element group number will be printed.

For all **post\_point** a point will be plotted in the gid files, with element group number 1000 + the index of the post point.

As a special option, you can set *switch* to **-separate\_index**. Then the mesh and results will be printed in separate files for GiD, numbered with *index*. The option comes handy when the mesh changes during the calculation; GiD cannot plot that if the mesh and results are in the same file.

As a further special option, you can set *switch* to **-separate\_sequential**. Then the mesh and results will be printed in separate files for GiD, number sequentially.

#### 6.294 control\_print\_gid\_batch *index switch*

If *switch* is set to **-yes** Tochnog calls GiD as batch program to generate some typical png files of results. This works i.c.w. a **control\_print\_gid** with the same index.

The following files are generated: mesh\_*index*.png, element\_group\_*index*.png, element\_group\_*index*.png, materi\_velocity\_integrated\_veliy\_*index*.png, materi\_stress\_sigyy\_*index*.png and ground-flow\_pressure\_total\_pressure\_to\_pres\_*index*.png.

For this GiD needs to be installed on your computer. You also need to take care that GiD can be found, so you need to adjust your PATH environment symbol.

#### 6.295 control\_print\_gid\_beam\_vectors *index switch*

If *switch* is set to **-yes**, force and moment vectors will be plotted for **-beam** and **-truss\_beam** elements. The force and moment vectors will be plotted perpendicular to the length direction and a user specified plane-normal vector, see **control\_print\_gid\_beam\_vectors\_normal**. The length of the plotted vectors measures the size of the forces and moment.

The vectors will be plotted as element result, so not as nodally averaged result.

Attention: this **control\_print\_gid\_beam\_vectors** is a special plotting option, to get each beam force and moment result as vector plot, with the possibility to influence the direction of the vectors with **control\_print\_gid\_beam\_vectors\_normal**. Default Tochnog plots the beam result already as scalar values for each beam element.

#### 6.296 control\_print\_gid\_beam\_vectors\_normal *index normal\_x normal\_y normal\_z*

This record gives you the possibility to influence the plane in which the moment vectors generated by the **control\_print\_gid\_beam\_vectors** will be plotted. In fact this **control\_print\_gid\_beam\_vectors\_normal** specifies the normal to the plotting plane. If this **control\_print\_gid\_beam\_vectors\_normal** is not specified then **0 0 1** is taken

as normal.

### 6.297 **control\_print\_gid\_contact\_spring2** *index number\_of\_nodes*

Set *number\_of\_nodes* to 2 if you want to draw **contact\_spring2** with two nodes, and to 1 if you want to draw **contact\_spring2** with one node. Default, if **control\_print\_gid\_contact\_spring2** is not specified, then 1 node is used.

### 6.298 **control\_print\_gid\_coord** *index switch*

If *switch* is set to **-yes** the coordinates of nodes is plotted in gid. If *switch* is set to **-no** the coordinates of nodes is not plotted in gid. Default *switch* is set to **-yes**.

### 6.299 **control\_print\_gid\_dof** *index initialisation\_name\_0 initialisation\_name\_1 ...*

When you specify this record only the solution fields *initialisation\_name\_0*, *initialisation\_name\_1* etc will be printed to the gid files. So the files become smaller in size. This is especially convenient for very large calculations. The names *initialisation\_name\_0*, *initialisation\_name\_1* are names from the initialisation part like **-condif temperature**, **-materi velocity**, **-materi stress** etc. In case you do not want any field to be printed in the gid file use **control\_print\_gid\_dof index -none**.

See also **control\_print\_gid\_other**.

### 6.300 **control\_print\_gid\_dof\_calcul** *index calcul\_0 calcul\_1 ...*

When you specify this record only the post fields *calcul\_0*, *calcul\_1* etc will be printed to the gid files. So the files become smaller in size. This is especially convenient for very large calculations. See **post\_calcul\_label** for the allowed names of *calcul\_0*, *calcul\_1* etc. In case you do not want any post field to be printed in the gid file use **control\_print\_gid\_dof\_calcul index -none**.

See also **control\_print\_gid\_other**.

### 6.301 **control\_print\_gid\_element\_group** *index element\_group\_0 element\_group\_1 ...*

Select specific element groups for the gid files. If this record is not specified all element groups will be used.

### 6.302 `control_print_gid_element_mpc` *index switch*

If *switch* is set to **-yes** also elements which have mpc'd nodes will be printed in the gid files. If *switch* is set to **-no** elements which have mpc'd nodes will not be printed in the gid files. Default, if `control_print_gid_element_mpc` is not specified, *switch* is set to **-yes**.

### 6.303 `control_print_gid_empty` *index switch*

If *switch* is set to **-yes**, empty elements will be shown in GID plots. If *switch* is set to **-no**, empty elements will not be shown. Default *switch* is set to **-no**.

See also `element_empty`.

### 6.304 `control_print_gid_group` *index switch*

If *switch* is set to **-yes** the element groups are plotted in gid as result field; in gid you can do a `contour_fill` to visualize this result field. If *switch* is set to **-no** the element groups are not plotted in gid as result. Default *switch* is set to **-yes**.

### 6.305 `control_print_gid_mesh_activate_gravity` *index switch*

See also `mesh_activate_gravity_time`.

### 6.306 `control_print_gid_method` *index method*

If *method* is set to **-node**, results will be written for global nodes to the gid files. Gid will interpolate between the nodes, to fill contour plots, etc. Hence, you get continuous plots fields.

If *method* is set to **-element**, results will be written element-by-element to the gid files, so that any discontinuity in fields can be seen. The results will be written using the integration point values.

If *method* is set to **-element\_average**, results will be written element-by-element to the gid files, so that any discontinuity in fields can be seen. The results will be written using the average of the integration point values.

If *method* is set to **-node\_element**, results will be written with continuous fields to the gid files, but at group jumps discontinuous fields are allowed.

For **-element** and **-node\_element** gid cannot plot some results like 'contour fill' for all elements if there are several type of elements (quad4, tria3, ...) in the mesh. You can only

select on specific element type for the plot.

If this **control\_print\_gid\_method** record is not specified then *method* is set to **-node**. If **global\_element\_dof** is set to **-no** the element-by-element stresses are not available, so then **-element\_average** and **-node\_element** should not be used.

### 6.307 control\_print\_gid\_node\_method *index method*

If *method* is set to **-node**, these coordinates are written. If *method* is set to **-node\_start\_refined**, these coordinates are written. If *method* is set to **-node\_deformed\_mesh**, these coordinates are written. Default *method* is **-node\_start\_refined**.

### 6.308 control\_print\_gid\_other *index switch*

If *switch* is set to **-yes** also other things like boundary conditions, mesh deformation etc. are printed in the gid files. If *switch* is set to **-no** these other things are not printed in the gid files. Default *switch* is set to **-yes**.

### 6.309 control\_print\_gid\_save\_difference *index switch*

If *switch* is set to **-yes** then data differences relative to a saved status will be plotted. See **control\_data\_save**.

### 6.310 control\_print\_gid\_safety\_slip\_critical *index switch*

If *switch* is set to **-yes**, then for a safety analysis with **control\_safety\_slip** only the critical slip surface will be plotted. Default, if *switch* is not set, all evaluated slip surfaces will be plotted. The critical surface is either determined over all safety surfaces, or otherwise in case sets are specified a critical surface is determined for each set.

Furthermore, always the normal stresses and shear stresses on the slip surfaces will be plotted.

### 6.311 control\_print\_gid\_smooth\_dof *index dof\_0 dof\_1 ...*

This option allows you to smooth results in gid files. With *dof\_0 dof\_1 ...* you specify the dof's to be smoothed. As a special option you can specify **-all** so that all dof's will be smoothed.

The smoothing is done a number of times, with increasing smooth results. You can specify this number of times with the optional **control\_print\_gid\_smooth\_n**; if you don't

specify this optional number of smoothings it is done 10 times.

### 6.312 **control\_print\_gid\_smooth\_n** *index number\_of\_smoothings*

See **control\_print\_gid\_smooth\_dof**.

### 6.313 **control\_print\_gid\_spring2** *index number\_of\_nodes*

Set *number\_of\_nodes* to 2 if you want to draw **spring2** with two nodes, and to 1 if you want to draw **spring2** with one node. Default, if **control\_print\_gid\_spring2** is not specified, then **print\_gid\_spring2** is used.

### 6.314 **control\_print\_gid\_truss\_vector** *index switch*

Same as **control\_print\_gid\_beam\_vector**, however now for the normal force in **-truss** and **-truss\_beam** elements.

Attention: this **control\_print\_gid\_truss\_vector** is a special plotting option, to get the truss force result as vector plot, with the possibility to influence the direction of the vectors with **control\_print\_gid\_truss\_vector\_normal**. Default Tochnog plots the truss force result already as scalar values for each truss element.

### 6.315 **control\_print\_gid\_truss\_vector\_normal** *index normal\_x normal\_y normal\_z*

Same as **control\_print\_gid\_beam\_vectors\_normal**, however now for the normal force in **-truss** and **-truss\_beam** elements.

### 6.316 **control\_print\_gmsh** *index switch*

We discuss as an example the printed file naming convention if the input file name is **excavation.dat**

If *switch* is set to **-yes** the results are printed into the **excavation.msh** file. In case the mesh (elements and nodes) have not been printed before in this file, the file will be emptied, and the mesh will be printed. This will also be done if the mesh is changed.

If *index* is 100 and *switch* is set to **-separate\_index** then the mesh and results are printed in the file is **excavation\_100.msh**.

If *switch* is set to **-separate\_sequential** then the mesh and results are printed in the files **excavation\_0.msh**, **excavation\_1.msh**, etc. So each time that a **control\_print\_gmsh** with **-separate\_sequential** is evaluated a new file is generated with number increased by one.

A dummy point element is put in each node in the gmsh file. Gmsh needs that for plotting vector fields in the nodes. The dummy element group 1234 is used for these dummy point elements. You can suppress these dummy point elements by setting **control\_print\_gmsh\_dummy** to **-no**.

All element data starts with **element\_** in the plots. All node data starts with **node\_** in the plots.

Scalar data with more then one value is given the extension **\_0**, **\_1** etc. for each of the values. For example the record **node** (which contains coordinates in each space direction) is plotted as scalar **node\_0**, **node\_1** and **node\_2** which contain the x-coordinate, y-coordinate and z-coordinate respectively. For example the record **group\_groundflow\_permeability** (which contains permeability in each space direction) is plotted as scalar **group\_groundflow\_0**, **group\_groundflow\_1** and **group\_groundflow\_2** which contain the x-permeability, y-permeability and z-permeability respectively.

For nodes the presence in geometries is plotted as **node\_geometry\_\***. For elements the presence in geometries is plotted as **element\_geometry\_\***.

You can plot this file with the program **gmsh** ; see <http://www.geuz.org/gmsh> . You can also plot this file with the program **mecway** ; see <https://mecway.com/> .

See also **input\_gmsh**.

### 6.317 control\_print\_gmsh\_dummy *index switch*

See **control\_print\_gmsh**.

Default, if this record is not set and **print\_gmsh\_dummy** is not specified, *switch* is set **-yes**.

### 6.318 control\_print\_gmsh\_element\_data *index switch*

If you set *switch* to **-yes** data for elements (like element strains, stresses, etc.) is written averaged over the element; this corresponds to **ElementData** in the gmsh format.

If you set *switch* to **-no** this data is written for all element nodes; this corresponds to **ElementNodeData** in the gmsh format.

Default, if this record is not set, *switch* is set **-yes**.

### 6.319 **control\_print\_gmsh\_node\_method** *index method*

If *method* is set to **-node**, these coordinates are written. If *method* is set to **-node\_start\_refined**, these coordinates are written. If *method* is set to **-node\_deformed\_mesh**, these coordinates are written.

### 6.320 **control\_print\_history** *index data\_item\_name\_0 data\_item\_index\_0 number\_0 ...*

Print the time history for each of the sets *data\_item\_name\_0 data\_item\_index\_0 number\_0 ...*.

For example, if **-node\_dof** is used, *number\_0* is one of the names of **dof\_label** (eg **-velx**).

For example, if **-node\_dof\_calcul** is used, *number\_0* is one of the names of **post\_calcul\_label** (eg **-aept**).

Otherwise, *number\_0* should be an integer specifying the number of the value in the record (for instance number 2 means the third value).

The following history is printed in the file `node_dof_112_temp.his`

```
control_print_history 0 -node_dof 112 -temp
```

### 6.321 **control\_print\_history\_factor** *index factor\_0 factor\_1 ...*

Optionally specify a multiplication factor for each of the data item of **control\_print\_history**. This can, by example, be convenient if you want to change to sign or so. If you specify this record, a factor should be given for each data item.

### 6.322 **control\_print\_history\_relative\_time** *index tr*

If you specify this record, the time printed in the history files will not be the actual time, but instead the actual time minus the relative time *tr*. This is especially convenient when something happens suddenly after a long time, in which case the time-axis in the history plot would be not clear. Using this relative time the time-axis in the plots will become clear (since the long initial time is not part of the time axis).

### 6.323 `control_print_history_smooth` *index smooth\_0 smooth\_1 ...*

You can smooth history results with this option. Each of *smooth\_0**smooth\_1* etc. represent an integer number for each data value printed with **control\_print\_history**. By example if *smooth\_0* is 10, for the first data value the average of the last 10 values will be printed (as opposed to the current value). You should specify an integer for each of the data values being printed. As a special option you can specify one integer only which then will be used for all data values being printed. The smoothed results will be printed in a separate history file starting with **smooth**.

### 6.324 `control_print_interface_stress` *index switch*

#### *2D analysis*

This option prints in 2D the interface stresses through a set of interfaces starting at place *x\_start, y\_start* and ending at *x\_end, y\_end* as specified in **control\_print\_interface\_stress\_coordinates**. The *switch* needs to be set to **-separate\_index** or **-separate\_sequential**. The stresses are printed in the file `interface_stress.index`. The first column in the file is the distance from the start point. The following columns contain `interface_sign` and `interface_sigt`. A line is written for each node of each interface element. Crossing interfaces are not allowed. From the start point up to the end point the interfaces needs to be connected without gaps.

#### *3D analysis*

This option prints in 3D the average interface stresses in the middle of interface elements. The *switch* needs to be set to **-separate\_index** or **-separate\_sequential**. The interface element middles and average stresses are printed in the file `interface_stress.index`. The first three columns in the file are the coordinates of the middle of the interface element. The following columns contain `interface_sign` and `interface_sigt1` and `interface_sigt2`. A line is written for each interface element. If you specify **control\_print\_interface\_stress\_3d\_geometry** then only interfaces elements located on the geometry will be printed. If you don't specify **control\_print\_interface\_stress\_3d\_geometry** then all interfaces elements will be printed. You can specify the order of printing of the interfaces in the file with *method* in **control\_print\_interface\_stress\_3d\_order**. If you set *order* to **-x** the interfaces will be ordered according to x-coordinate. If you set *order* to **-y** the interfaces will be ordered according to y-coordinate. If you set *order* to **-z** the interfaces will be ordered according to z-coordinate. If you don't use **control\_print\_interface\_stress\_3d\_order** the interfaces will be ordered according to element number.

### 6.325 `control_print_interface_stress_2d_coordinates` *index x\_start y\_start x\_end y\_end*

For 2D only. See **control\_print\_interface\_stress**.

**6.326 control\_print\_interface\_stress\_3d\_geometry** *index geometry\_item\_name geometry\_item\_index*

For 3D only. See **control\_print\_interface\_stress**.

**6.327 control\_print\_interface\_stress\_3d\_order** *index order*

For 3D only. See **control\_print\_interface\_stress**.

**6.328 control\_print\_materi\_stress\_force** *index method*

This option prints forces and moments as calculated by **post\_calcul\_materi\_stress\_force**. It prints in special purpose ascii files, convenient for further external postprocessing. For example, the name of the file will be **materi\_stress\_force.100** if the *index* is 100. The files themselves will contain comments explaining the detailed structure of the files.

The *method* can be set either to **-all** if all results should be printed in the file (so including the averaged results) or to **-primary** if only the primarily calculated results should be printed in the file (so not including the averaged results).

**6.329 control\_print\_mesh\_dof** *index switch*

See **print\_mesh\_dof**.

**6.330 control\_print\_node** *index data\_item\_name number\_0 number\_1 ...*

With this record you can print nodal data like **node\_dof**, **node\_dof\_calcul** etc. to files. As an example in 2D you can use **control\_print\_node index -node\_dof -velx -velx** to get the files **velx.index** and **vely.index**; these files contain in columns for all nodes x y velx and x y vely.

For *data\_item\_name* you can apply any nodal data record for which the name starts with **node**. For *number\_0 number\_1* you can specify which parts of the data record should be printed; you can either specify numbers 0, 1, etc. or for **node\_dof** you can specify the names of **dof\_label** like **-vely**, **-vely** etc., or for **node\_dof\_calcul** you can specify the names of **post\_calcul\_label** like **-to\_pres**, **-dy\_pres** etc.

### 6.331 **control\_print\_node\_angular** *index switch\_x switch\_y switch\_z*

With this record you can specify that an angle will be included in the files (in stead of coordinates). With *switch\_x switch\_y switch\_z* set to **-yes -yes -no** the angle will measure the number of degrees from the positive global x-coordinate directed to the positive global y-direction. With *switch\_x switch\_y switch\_z* set to **-no -yes -yes** the angle will measure the number of degrees from the positive global y-coordinate directed to the positive global z-direction. With *switch\_x switch\_y switch\_z* set to **-yes -no -yes** the angle will measure the number of degrees from the positive global x-coordinate directed to the positive global z-direction. In 1D you cannot use this **control\_print\_node\_angular** record. In 2D you should not specify *switch\_z* and you can only use **-yes -yes**.

The middle point of the axes in which the angle is determined should be specified with **control\_print\_node\_angular\_middle**. For example in 2D the angle follows from  $\tan(\text{angle}) = \frac{y-y\_middle}{x-x\_middle}$ . In 1D you cannot use this **control\_print\_node\_angular\_middle** record. In 2D you should not specify *z\_middle* and you should only specify *x\_middle* *y\_middle*.

See also **control\_print\_node**.

### 6.332 **control\_print\_node\_angular\_middle** *index x\_middle y\_middle z\_middle*

See **control\_print\_node\_angular**.

### 6.333 **control\_print\_node\_geometry** *index geometry\_item\_name geometry\_item\_index*

With **control\_print\_node\_geometry** you can restrict the printing to be done only on nodes located on the specified geometry. See also **control\_print\_node**.

### 6.334 **control\_print\_node\_sort** *index sort\_method*

With **control\_print\_node\_sort** you can set if the printed results should be sorted. In case you use **-angular** for **control\_print\_node\_method**, you can set the *sort\_method* to **-angle**. Otherwise you can set the sort method to **-x**, **-y** or **-z** (**-y** is only allowed for 2D or 3D, and **-z** is only allowed for 3D). The results will be sorted starting from small values (of the **-angle**, **-x**, **-y** or **-z**) up to high values.

### 6.335 **control\_print\_node\_zero** *index switch*

With **control\_print\_node\_zero** you can suppress or activate printing of results with value zero. If you set *switch* to **-yes** then zero valued results will also be printed. If you set *switch* to **-no** then zero valued results will not be printed. Default *switch* is **-yes**. See also **control\_print\_node**.

### 6.336 **control\_print\_number\_iterations** *index switch*

If *switch* is set to **|bf -yes**, Tochnog will print the iteration number while doing equilibrium iterations in a time step. This comes convenient in very large calculations, where you want to monitor the evolution of the calculation.

### 6.337 **control\_print\_partialname** *index data\_item\_name\_0 data\_item\_name\_1 ...*

This printing command is similar to the normal **control\_print** command. With this record, however, all records starting with *data\_item\_name\_0*, *data\_item\_name\_1*, etc. will be printed. Thus, for example, **control\_print\_partialname 10 -element** will print all records stating with **element** (as opposed to **control\_print 10 -element** will only print the **element** record).

### 6.338 **control\_print\_tecplot** *index switch*

If *switch* is set to **-yes** a tecplot plot file is printed, and each time results are added to the same file. You can also set *switch* to **-separate\_index**; then a new file using the index number will be printed. And also you can set *switch* to **-separate\_sequential**; then sequential tecplot files will be printed.

These files contain:

- the primary doffields from **node\_dof**
- post calculated results from **node\_dof\_calcul**

Tecplot uses **zones** to collect data. Zones with nodal results are given names **nodal\_....**. Zones with element averaged results are given names **element\_averaged\_....**. Tecplot uses a strandid integer to select which data is visualised. Tochnog generates in the tecplot file this strandid as follows:

- for nodal results the strandid is the group number and extra 1 is placed at the end

- for element averaged results the strandid is the group number and extra 2 is placed at the end

For example for group 100, the strandid is 1001 for nodal results, and the strandid is 1002 for element averaged results.

Tecplot files are less complete as GID files and GMSH files. Tecplot files can be plotted with the tecplot program, a trademark of Amtec Eng., Inc.

### 6.339 control\_print\_vtk *index switch*

Activate printing of results in the Visual Toolkit unstructured grid format, which can be plotted by the **paraview** plotting program. See **www.paraview.org**.

For example, if the input file name is **excavation.dat** and *index* is 100 and *switch* is set to **-separate\_index** then results are printed in the file is **excavation100.vtk**.

For example, if the input file name is **excavation.dat** and *switch* is set to **-separate\_sequential** then results are printed in the files is **excavation0.vtk**, **excavation1.vtk**, etc.

In **paraview** elements are called 'cells' and nodes are called 'points'.

How to get a nice contour plot for the yy-stress:

- **File open** ..... choose file and hit apply button
- **Coloring** ..... choose node\_materi\_stress and set 4 in stead of magnitude
- **Edit** hit the **Choose preset** button and select something nice.
- **Edit** set **number of table values** to e.g. 80
- **Color Legend** change legend text etc.
- **File Save Screenshot** save picture

How to get a vector plots for velocities:

- **File open** ..... choose file and hit **apply** button
- **Glyph** add glyphs for vectors
- **Glyph type** choose **arrow**
- **Scale mode** choose **vectors**
- **Set scale factor** choose factor to get nice vector lengths
- **Coloring** choose node\_materi\_velocity and choose magnitude

How to find the number of elements depicted in the plot:

- Split the screen at the top right of the layout window, and select spreadsheet view on the second screen
- **View** and then **Selection display inspector**
- In the inspector select **ID** for **Cell labels** and **Point labels**
- Activate the small **select cells on** button in the layout
- With the left mouse button click and drag to select the cells

How to see only elements of a certain groups:

- In **Filters** select **Common** and then select **Threshold**
- In **Scalars** select **element\_group**
- In **Minimum** set the minimum group number that you want to see
- In **Maximum** set the maximum group number that you want to see
- In **Coloring** select the data that you want to see

#### 6.340 `control_print_vtk_coord` *index switch*

If *switch* is set to **-yes** the coordinates of nodes is plotted in vtk. If *switch* is set to **-no** the coordinates of nodes is not plotted in vtk. Default *switch* is set to **-yes**.

#### 6.341 `control_print_vtk_dof` *index initialisation\_name\_0 initialisation\_name\_1 ...*

When you specify this record only the solution fields *initialisation\_name\_0*, *initialisation\_name\_1* etc will be printed to the vtk files. So the files become smaller in size. This is especially convenient for very large calculations. The names *initialisation\_name\_0*, *initialisation\_name\_1* are names from the initialisation part like **-condif\_temperature**, **-materi\_velocity**, **-materi\_stress** etc. In case you do not want any field to be printed in the vtk file use `control_print_vtk_dof index -none`.

See also `control_print_vtk_other`.

### 6.342 **control\_print\_vtk\_dof\_calcul** *index calcul\_0 calcul\_1 ...*

When you specify this record only the post fields *calcul\_0*, *calcul\_1* etc will be printed to the vtk files. So the files become smaller in size. This is especially convenient for very large calculations. See **post\_calcul\_label** for the allowed names of *calcul\_0*, *calcul\_1* etc. In case you do not want any post field to be printed in the vtk file use **control\_print\_vtk\_dof\_calcul** *index* -none.

See also **control\_print\_vtk\_other**.

### 6.343 **control\_print\_vtk\_empty** *index switch*

If *switch* is set to -yes, empty elements are included in the vtk file. If *switch* is set to -no, empty elements are not included in the vtk file. Default, if **control\_print\_vtk\_empty** is not specified, *switch* is set to -yes.

### 6.344 **control\_print\_gid\_group** *index switch*

If *switch* is set to -yes the element groups are plotted in vtk as result field. If *switch* is set to -no the element groups are not plotted in vtk as result. Default *switch* is set to -yes.

### 6.345 **control\_print\_vtk\_node\_method** *index node\_type*

If *method* is set to -node, these coordinates are written. If *method* is set to -node\_start\_refined, these coordinates are written. If *method* is set to -node\_deformed\_mesh, these coordinates are written.

### 6.346 **control\_print\_vtk\_other** *index switch*

If *switch* is set to -yes also other things like boundary conditions, mesh deformation etc. are printed in the vtk files. If *switch* is set to -no these other things are not printed in the vtk files. Default *switch* is set to -yes.

### 6.347 **control\_repeat** *index number\_of\_repeats control\_index*

If *number\_of\_repeats* is larger than 0 the calculation repeats from the *control\_index*. The value of *number\_of\_repeats* is decreased by 1.

A first application is to do many time steps, but print only once in a while:

```

control _timestep 10 1. 100. ...
control _print 20 -node _dof ...
control _repeat 30 80 10

```

In the latter example, first 100 timesteps are taken, then results for **node** **\_dof** are printed; this is repeated 80 times.

Also, this **control** **\_repeat** can typically be used to perform a number of refinements combined with time stepping to a new, refined, solution. This is done a fixed number of times.

In case the repeat jumps back to a **control** **\_timestep** record for which the index equals *control\_index*, then that the previous timestep will be used (instead of the timestep specified by the **control** **\_timestep** record).

See also **control** **\_repeat** **\_until** **\_item**.

**6.348** **control** **\_repeat** **\_save** *index data\_item\_name\_0 data\_item\_index\_0*  
*data\_item\_number\_0 data\_item\_name\_1 data\_item\_index\_1 data\_item\_number\_1*  
 ...

This record specifies data that should be saved while repeats are performed with **control** **\_repeat**. The saved results are stored in the records **repeat** **\_save** **\_result** (subsequent repeats write in subsequent indices of **repeat** **\_save** **\_result**).

**6.349** **control** **\_repeat** **\_save** **\_calculate** *index switch*

Perform a statistical analysis on data of **repeat** **\_save** **\_result**. The statistical results are placed in **repeat** **\_calculate** **\_result**. The average value and variance will be calculated.

**6.350** **control** **\_reset** **\_dof** *index dof\_0 dof\_1 ...*

The dof's as specified in this record are set to a some new value. For example, *dof\_0* is **-sigxx**, etc. As a special option you can use **-all** to reset all dof's.

With **control** **\_reset** **\_value** **\_constant** you can specify the new value to which the dof's should be set. Additionally you can specify values depending on space coordinates with **control** **\_reset** **\_value** **\_linear** etc. The records **control** **\_reset** **\_value** **\_constant**, **control** **\_reset** **\_value** **\_linear** etc. can be arbitrarily combined so that complex dependency of the value of space coordinates is possible. If none of these records is specified then a new value 0 is used.

As a typical example, you can set displacements and strains to zero in a geotechnical calculation, with an **-updated** material description, after the gravity load has been applied. In

this way the strains for further deformations can be distinguished more clearly.

The dof's will be reset on all nodes of elements which are completely inside the geometry specified in **control\_reset\_geometry**, or of elements which have all their nodes specified in **control\_reset\_node**.

As a special option for groundflow calculations, you can set an dof to **-total\_pressure** to reset the physical groundflow pore pressure (total pressure) .

Attention: this **control\_reset\_dof** should not be used to reset displacements (or velocity integrated) if also **support\_edge\_normal** is present. This is because those **support\_edge\_normal** supports calculate forces directly from total displacements, and so you would in fact set the support forces also to zero. Also in the presence of interface elements the displacements (or velocity integrated) should not be reset. Normal isoparametric elements use an incremental formulation for stresses however (new stress = old stress + incremental stress from stiffness), so that resetting displacements to zero does not influence the stresses.

Attention: with this **control\_reset\_dof** option you cannot reset the strains, stresses, forces, etc. in structural elements (springs, interfaces, trusses, ...) This option only works for isoparametric elements.

#### 6.351 **control\_reset\_element\_dof** *index switch*

If *switch* is set to **-yes** only dofs in **element\_dof** and **element\_intpnt\_dof** will be set; dofs in **node\_dof** will not be set.

#### 6.352 **control\_reset\_element\_group** *index element\_group\_number\_0 element\_group\_number\_1 ...*

Specifies the specific element groups on which the **control\_reset\_dof** record with the same index should be applied. If this record is not specified, the **control\_reset\_dof** record will be done for all element groups (in the specified geometry).

#### 6.353 **control\_reset\_geometry** *index geometry\_item\_name geometry\_item\_index*

Specifies the geometry on which the **control\_reset\_dof** record with the same index should be applied.

### 6.354 **control\_reset\_interface** *index geometry\_item\_name geometry\_item\_index*

Reset all interface data like strains, stresses, etc. to 0 for interface elements located in the geometry with name *geometry\_item\_name* and index *geometry\_item\_index*.

### 6.355 **control\_reset\_interface\_strain** *index geometry\_item\_name geometry\_item\_index*

Reset all interface strains to 0 for interface elements located in the geometry with name *geometry\_item\_name* and index *geometry\_item\_index*. The interface stresses at this moment of resetting will be remembered by Tochnog. In the next time steps the new interface strains start with 0, and change when the interfaces deform further. And in the next time steps the new interface stresses are calculated from the interface stresses at this moment of resetting plus stress due to additional deformation (from the specified stiffness properties).

### 6.356 **control\_reset\_node** *index node\_0 node\_1 ...*

Specifies nodes on which the **control\_reset\_dof** record with the same index should be applied.

### 6.357 **control\_reset\_value\_constant** *index value*

Specifies the value to which dof's of the **control\_reset\_dof** record are reset. A constant *value* will be used.

### 6.358 **control\_reset\_value\_dof** *index dof*

This record allows you to make the dofs of **control\_reset\_dof** dependent on a specified *dof* of this **control\_reset\_value\_dof** record. The dependency should be given in table form with **control\_reset\_value\_dof\_diagram**.

By example you can make a **-hyhis0** in the hypo laws dependent on the vertical stress **-sigyy**:

- **control\_reset\_dof 10 -hyhis0**
- **control\_reset\_value\_dof 10 -sigyy**
- **control\_reset\_value\_dof\_diagram 10 -1.e2 0.4 -2.e2 0.38 -1.e3 0.3**

This specifies that for vertical stress -1.e2 the void ratio is 0.4, for vertical stress -2.e2 the void ratio is 0.38, etc.

### 6.359 **control\_reset\_value\_dof\_diagram** *index ....*

See **control\_reset\_value\_dof**.

### 6.360 **control\_reset\_value\_exponent** *index $a_x b_x c_x d_x e_x a_y b_y c_y d_y e_y a_z b_z c_z d_z e_z$*

Specifies the exponential space distribution to which dof's of the **control\_reset\_dof** record are reset. The dependency  $a_x e^{\frac{b_x + c_x x}{d_x + e_x x}} + a_y e^{\frac{b_y + c_y y}{d_y + e_y y}} + a_z e^{\frac{b_z + c_z z}{d_z + e_z z}}$  will be used. In 1D only  $a_x b_x c_x d_x e_x$  should be specified. In 2D only  $a_x b_x c_x d_x e_x a_y b_y c_y d_y e_y$  should be specified.

### 6.361 **control\_reset\_value\_linear** *index $a_x a_y a_z$*

Specifies the linear space distribution to which the dof's of the **control\_reset\_dof** record are reset. The dependency  $a_x x + a_y y + a_z z$  will be used. In 1D only  $a_x$  should be specified. In 2D only  $a_x a_y$  should be specified.

### 6.362 **control\_reset\_value\_logarithmic\_first** *index $a_x b_x c_x d_x e_x a_y b_y c_y d_y e_y a_z b_z c_z d_z e_z$*

Specifies the logarithmic space distribution to which dof's of the **control\_reset\_dof** record are reset. The dependency  $a_x \ln(\frac{b_x + c_x x}{d_x + e_x x}) + a_y \ln(\frac{b_y + c_y y}{d_y + e_y y}) + a_z \ln(\frac{b_z + c_z z}{d_z + e_z z})$  will be used. In 1D only  $a_x b_x c_x d_x e_x$  should be specified. In 2D only  $a_x b_x c_x d_x e_x a_y b_y c_y d_y e_y$  should be specified.

### 6.363 **control\_reset\_value\_logarithmic\_second** *index $a_x b_x c_x d_x e_x f_x g_x a_y b_y c_y d_y e_y f_y g_y a_z b_z c_z d_z e_z f_z g_z$*

Specifies the logarithmic space distribution to which dof's of the **control\_reset\_dof** record are reset. The dependency  $(a_x + b_x)(e^{c_x \ln(d_x(x+e_x)/f_x)}) + g_x + (a_y + b_y)(e^{c_y \ln(d_y(y+e_y)/f_y)}) + g_y + (a_z + b_z)(e^{c_z \ln(d_z(z+e_z)/f_z)}) + g_z$  will be used. In 1D only  $a_x b_x c_x d_x e_x f_x g_x$  should be specified. In 2D only  $a_x b_x c_x d_x e_x f_x g_x a_y b_y c_y d_y e_y f_y g_y$  should be specified.

### 6.364 **control\_reset\_value\_multi\_linear** *index $z_0 value_0 z_1 value_1 \dots$*

Specifies the multi-linear space distribution in vertical direction to which the dof's of the **control\_reset\_dof** record are reset. A multilinear table of value versus  $z$  coordinate should be given; at  $z_0$  the value is  $value_0$  etc. The  $z_0, z_1$  etc. should have increasing values from low to high; the values should cover all coordinates in the FE mesh for with the reset is done. In 1D not a  $z$  coordinate but  $x$  coordinate is used instead. In 2D not a  $z$  coordinate but  $y$  coordinate is used instead.

### 6.365 **control\_reset\_value\_power** *index a<sub>x</sub>b<sub>x</sub>a<sub>y</sub>b<sub>y</sub>a<sub>z</sub>b<sub>z</sub>*

Specifies the power space distribution to which the dof's of the **control\_reset\_dof** record are reset. The dependency  $a_x x^{b_x} + a_y y^{b_y} + a_z z^{b_z}$  will be used. In 1D only  $a_x b_x$  should be specified. In 2D only  $a_x b_x a_y b_y$  should be specified.

### 6.366 **control\_reset\_value\_method** *index method*

If *switch* is set to **-multiply** the values as specified by **control\_reset\_value** etc. are used as relative factor by which the dof's are changed. So for example if 0.1 is given in **control\_reset\_value\_constant**, then the dof's will be multiplied with 0.1.

If *switch* is set to **-add** the values as specified by **control\_reset\_value** etc. are used as additional values by which the dof's are changed. So for example if 0.1 is given in **control\_reset\_value\_constant**, then the dof's will be added with 0.1.

### 6.367 **control\_reset\_value\_square\_root** *index a<sub>x</sub>b<sub>x</sub>c<sub>x</sub>a<sub>y</sub>b<sub>y</sub>c<sub>y</sub>a<sub>z</sub>b<sub>z</sub>c<sub>z</sub>*

Specifies the power space distribution to which the to which dof's of the **control\_reset\_dof** record are reset. The dependency  $a_x \sqrt{b_x + c_x x} + a_y \sqrt{b_y + c_y y} + a_z \sqrt{b_z + c_z z}$  will be used. In 1D only  $a_x b_x$  should be specified. In 2D only  $a_x b_x a_y b_y$  should be specified.

### 6.368 **control\_restart** *index switch*

If *switch* is set to **-yes** then the calculation continues with the undeformed mesh. The dof's (in the **node\_dof** records) are reset to the initial values. And **time\_current** is set to the initial time.

This allows you to calculate some path dependent behavior completely from the start with a refined mesh.

### 6.369 **control\_safety\_slip** *index switch*

If *switch* is set to **-yes** a slip safety factor calculation will be performed with the method as described in [4]. The calculated safety factor  $F_s$  is:

$$F_s = \frac{\int \tau_{mc} dA}{\int \tau dA}$$

where  $\tau_{mc}$  is the maximum possible shear stress according to the mohr-coulomb condition using the actual normal stress,  $\tau$  is the actual shear stress and  $dA$  is the surface area in

the integral. The advantage of this safety factor definition is that it can be evaluated at any stress state, for example the gravity stress state, without any further timesteps with friction angle and cohesion reduction. The definition simply compares the actual current shear stress relative to the maximum possible shear stress following from mohr-coulomb and the current normal stresses.

The user needs to specify over which surface the integration of the safety factor needs to be performed. See **safety\_slip\_circle\_grid\_\***, etc.

A critical slip surface will be calculated for each set of **safety\_slip\_circle\_grid\_\***, etc. (thus for each separate index of these a critical surface will be calculated). You can specify also **safety\_slip\_set** however, which defines the indices of **safety\_slip\_circle\_grid\_\***, etc. belonging to a specific set. The overall minimal safety factor will be determined for all safety geometries belonging to the set.

This **control\_safety\_slip** is available for **group\_materi\_plasti\_mohr\_coul**, **group\_materi\_plasti\_mohr\_coul\_direct**, **group\_materi\_plasti\_druck\_prag** and **group\_materi\_plasti\_hypo\_wolffersdorff**.

As a special option you can set the *switch* not to **-yes** but to a number 1, 2, 3, .. instead. Then this number 1, 2, 3, ... is used by tochnog as the number of automatic safety calculations of the critical slip surface. For example if you use slip circles (specified by middle points and radii) after the first safety calculations a specific middle point and radius will have the lowest safety factor. Then in the next safety calculation tochnog will reduce the area of middle points and the set of radii to a smaller zone around that critical middle point and radius. With this smaller zone a new safety analysis will lead to a new critical middle point and radius somewhere in the reduced zone. Then again a smaller zone will be used, leading to again a new critical middle point and radius, etc. etc. This repetition of reducing the zone of middle points and radii will be done such many times as set in the number, so 1, 2, 3, ... Typically the number 2 could be used.

Slip surfaces will be drawn in GID plots (see **control\_print\_gid** for GID plotting). For each slip surfaces the safety factor can be plot. Moreover, also a local safety factor can be plot, which is the local ratio of shear stress and maximum possible shear stress.

Slip surfaces crossing a boundary with prescribed displacements (or velocities) non valid since the slip velocities are in general not compatible with the prescribed velocities on such boundary.

### 6.370 **control\_slide\_damping\_apply** *index switch*

If *switch* is set to **-yes** then any **slide\_damping** records will be applied. If *switch* is set to **-no** then any **slide\_damping** records will be not applied. Default if **control\_slide\_damping\_apply** is not specified then *switch* is **-yes**.

### 6.371 **control\_slide\_plasti\_apply** *index switch*

If *switch* is set to **-yes** then any **slide\_plasti\_\*** records will be applied. If *switch* is set to **-no** then any **slide\_plasti\_\*** records will be not applied. Default if **control\_slide\_plasti\_apply** is not specified, **plasti\_apply** or **control\_plasti\_apply** will be used.

### 6.372 **control\_slide\_stiffness\_apply** *index switch*

If *switch* is set to **-yes** then any **slide\_stiffness** records will be applied. If *switch* is set to **-no** then any **slide\_stiffness** records will be not applied. Default if **control\_slide\_stiffness\_apply** is not specified then *switch* is **-yes**.

### 6.373 **control\_solver** *index solver\_type*

If *solver\_type* is set to **-diagonal** then only the main diagonal of the system matrix will be used for the solution of all dof's. This gives the program an explicit like structure. In fact, if **control\_timestep\_iterations** is set to 1, then a classical explicit finite element program is obtained.

If *solver\_type* is set to **-matrix\_iterative\_bicg** then the complete system matrix will be used for solution of the principal dof's (see the initialization section for an explanation on principal dof's). A diagonal Preconditioned Biconjugate Gradient method is applied.

If *solver\_type* is set to **-matrix\_pardiso** then the pardiso solver will be used for solution of the principal dof's.

If *solver\_type* is set to **-none** then only the matrices and right-hand sides are setup, but the equations are not really solved.

### 6.374 **control\_solver\_bicg\_error** *index error*

With *error* you set the termination error ratio between the initial and final error in the bicg iterations. Default *error* is set to **1.e-13**.

See also **solver\_bicg\_error**. This **control\_solver\_bicg\_error** record overrules **solver\_bicg\_error** if both are specified.

### 6.375 **control\_solver\_bicg\_restart** *index nrestart*

With *nrestart* you set the number of restarts in the bicg iterations. Default *nrestart* is set to 0.

See also **solver\_bicg\_restart**. This **control\_solver\_bicg\_restart** record overrules **solver\_bicg\_restart** if both are specified.

### 6.376 control\_solver\_bicg\_stop *index switch*

If *switch* is set to **-yes**, the calculation is stopped if the bicg solver does not converge. If *switch* is set to **-no**, the calculation is not stopped if the bicg solver does not converge. Default *switch* is set to **-yes**.

See also **solver\_bicg\_stop**. This **control\_solver\_bicg\_stop** record overrules **solver\_bicg\_stop** if both are specified.

### 6.377 control\_solver\_matrix\_save *index switch*

If *switch* is set to **-yes**, the solver saves and applies the decomposed matrix, but not in case Tochnog thinks for some reason that the matrix needs to be decomposed at each timestep. This can save CPU time, since further decompositions of the matrix are not required anymore (only backsubstitution to find the solution vector).

If *switch* is set to **-no**, the solver does not save the decomposed matrix.

If *switch* is set to **-always**, the solver saves and applies the decomposed matrix, even in case Tochnog thinks for some reason that the matrix needs to be decomposed at each timestep.

This option is only available in combination with the pardiso solver.

Side remark: Tochnog mostly uses a linear matrix in iterations (no plasticity effect in the matrix). Only in special cases like hypoplasticity, user supplied routines, etc. the current stiffness matrix is used.

### 6.378 control\_solver\_pardiso\_out\_of\_core *index switch*

If *switch* is set to **-yes** the pardiso solver is called with a 'out of core' option. See for further the pardiso solver in the the intel mkl library. Default *switch* is **-no**.

### 6.379 control\_solver\_pardiso\_ordering *index ordering*

Set the number *ordering* to one of the following:

- 0 The minimum degree algorithm.
- 2 The nested dissection algorithm from the METIS package.

- 3 The parallel (OpenMP) version of the nested dissection algorithm.

Default *ordering* is **3**. For more information see pardiso info at intel.

### 6.380 **control\_support\_edge\_normal\_damping\_apply** *index switch*

If *switch* is set to **-yes** then all **support\_edge\_normal\_damping** records will be applied. If *switch* is set to **-no** then all **support\_edge\_normal\_damping** records will not be applied. Default, if **control\_support\_edge\_normal\_damping\_apply** is not specified, then *switch* is set to **-yes**.

### 6.381 **control\_support\_edge\_normal\_stiffness\_freeze** *index switch*

If *switch* is set to **-yes**, tochnog freezes the stiffness forces generated by **support\_edge\_normal**. The stiffness forces remain at their present value and will not change anymore. A typical application is earthquake or vibration analysis where you first impose gravity including stiffness at supports, then freeze the forces at the supports, and then in the earthquake or vibration analysis use only damping at the supports to model absorbing boundaries which absorb further force changes at the boundaries.

```
( support properties )
support_edge_normal 10 ...
support_edge_normal_damping 10 ...
...
( calculate gravity stresses )
control_timestep 10 ...
control_support_edge_normal_damping_apply 10 -no
...
( freeze stiffness forces at boundary )
control_support_edge_normal_stiffness_freeze 20 -yes
...
( calculate earthquake or vibrations )
control_timestep 30 ...
control_support_edge_normal_damping_apply 30 -yes
control_inertia_apply 30 -yes
```

### 6.382 **control\_system\_call** *index integer\_value*

Specifying this record tochnog calls a system command. You need to program that command yourself. On linux provide a **tochnog\_system\_call.sh** file which is executable. On MS Windows provide a **tochnog\_system\_call.bat** file.

In the command you can place commands that you want to be executed. For example, if you put in the linux file the command **date >> system\_call.out** you get the output of the **date** command appended to **system\_call.out**. Another example is sending you an automatic email indicating that the calculation reached a certain point or is almost finished.

The command is called with *integer\_value* as first argument. You can use this integer value in your command (eg by using \$1 in the linux shell script command).

This command is executed at the end of each timestep and also at the end of each control index.

**6.383 control\_timestep** *index step\_size time\_increment step\_size time\_increment*  
...

These records define sets of time steps of size *step\_size* which are to be taken till the time is increased by *time\_increment*. In the example below time steps of 0.1 are taken from time 0.0 up to time 1.0. Then time steps of 0.2 are taken up to time 2.0

```
control_timestep 0 0.1 1. 0.2 1.
```

**6.384 control\_timestep\_adjust\_minimum\_iterations** *index switch*

If *switch* is set to **-yes** Tochnog will increase the minimum number of iterations in a timestep if it thinks that is helpful for the specific input file that you are running; this is done in combination with **control\_timestep\_iterations\_automatic**. If *switch* is set to **-no** Tochnog will not do so, and keep 2 as the minimum number of iterations. Default, if **control\_timestep\_adjust\_minimum\_iterations** is not specified, *switch* is set to **-yes**.

**6.385 control\_timestep\_iterations** *index number\_of\_iterations*

This sets a fixed number of equilibrium iterations in each time step (for time steps of the **control\_timestep** record with the same index). For many iterations, the time stepping is Euler implicit. For few iterations the time stepping becomes explicit. Default *number\_of\_iterations* is 2.

In dynamic analysis, with the default number of 2 iterations you gain numerical stability, at the expense of numerical damping however. To prevent this numerical damping use 1 iteration instead.

As an alternative, you can use **control\_timestep\_iterations\_automatic**.

### 6.386 **control\_timestep\_iterations\_automatic** *index ratio\_criterium minimal\_timestep maximum\_timestep*

After specification of this record, iterations will be performed until *ratio* in **post\_node\_rhside\_ratio** is less than *ratio\_criterium*. Typically, set *ratio\_criterium* to 0.001.

The time step size is increased if the number of iterations is substantially lower then the wished (preferred) number of iterations. The time step size is decreased if the number of iterations is substantially larger then the wished (preferred) number of iterations.

The time step specified in **control\_timestep** is used as initial step. The time step is not allowed to become higher then *maximum\_timestep*. The time step is not allowed to become lower then *maximum\_timestep*.

The initial step as specified in **control\_timestep**, should be sufficient small so that this automatic algorithm can fulfill the *ratio\_criterium* in that initial step.

After the iterations in a step are finished, Tochnog performs one extra iterations to update strains, stresses, etc with the last velocity fields. In this extra iteration also the **post\_node\_rhside\_ratio** will be recalculated, and thus may become different from the previous value that was used to determine if the iterations should be stopped.

See also **control\_timestep\_iterations\_automatic\_stop**, and **control\_timestep\_iterations\_automatic**.

### 6.387 **control\_timestep\_iterations\_automatic\_minimum\_maximum\_wished** *index minimum\_iterations maximum\_iterations wished\_iterations*

This sets the minimum number of allowed iterations, the maximum number of allowed iterations, and the wished (preferred) number of iterations for the automatic time stepping mechanism as specified by **control\_timestep\_iterations\_automatic** with the same index. The default for this record is 2 8 4. The maximum number of allowed iteration should be 2 or larger.

### 6.388 **control\_timestep\_iterations\_automatic\_stop** *index switch*

If you set *switch* in **control\_timestep\_iterations\_automatic\_stop** to **-yes** then the calculation does stop if the minimal timestep size is reached. If you set *switch* in **control\_timestep\_iterations\_automatic\_stop** to **-no** then the calculation does not stop if the minimal timestep size is reached, and the present timestepping will be finished.. If you set *switch* in **control\_timestep\_iterations\_automatic\_stop** to **-continue** then the calculation does not stop if the minimal timestep size is reached, and the present timestepping will not be finished.. Default, if **control\_timestep\_iterations\_automatic\_stop** is not specified, then *switch* is set to **-yes**.

### 6.389 **control\_timestep\_multiplier** *index multiplier maximum\_timestep*

If this record is specified, each new time step size is *multiplier* \* old time step size. The *step\_size* as specified in **control\_timestep** will only be used as the initial time step.

The timestep is not allowed to exceed the maximum specified timestep *maximum\_timestep*.

This option is handy to study physical processes which develop more slowly when time proceeds. A typical example is consolidation analysis in geotechnics.

### 6.390 **control\_timestep\_until\_data** *index data\_item\_name\_0 data\_item\_index\_0 data\_item\_number\_0 data\_item\_name\_1 data\_item\_index\_1 data\_item\_number\_1 ...*

With this record you can specify conditions for which the timesteps with the same index should be stopped. For each specified data item name, index and number you can specify a minimum value in **control\_timestep\_until\_minimum** and a maximum value in **control\_timestep\_until\_maximum**. A typical example:

```
control_timestep 10 ...
control_timestep_until_data 10 -post_point_dof 3 -velx
control_timestep_until_minimum 10 -120.
control_timestep_until_maximum 10 +120.
```

### 6.391 **control\_timestep\_until\_maximum** *index maximum\_0 maximum\_1 ...*

See **control\_timestep\_until\_data**.

### 6.392 **control\_timestep\_until\_minimum** *index minimum\_0 minimum\_1 ...*

See **control\_timestep\_until\_data**.

### 6.393 **control\_truss\_rope\_apply** *index switch*

If *switch* is set to **-no**, any truss rope data in the input file will be ignored. This is done for timestep records with the same index.

This option is convenient for testing your input file just linear, without the need to outcomment each and every part with truss rope data. See also **truss\_rope\_apply**.

#### 6.394 **control\_zip** *index switch*

If *switch* is set to **-yes** all **\*flavia\***, **\*msh**, **vtk**, **\*.plt** and **\*dbs** files are zipped with the **gzip** program. The **gzip** program should be installed on your computer.

This comes convenient in large calculation with lots of output, where you want to use results later and save disk space during the calculation.

#### 6.395 **convection\_apply** *switch*

If *switch* is set to **-yes**, the convection of a material with respect to the mesh is allowed. If *switch* is set to **-no**, the convection of a material with respect to the mesh is not allowed. This is done for all timesteps.

Default *switch* is set to **-no**. See also **control\_convection\_apply**.

#### 6.396 **convection\_stabilization** *switch*

Because of finite discretisation sometimes unrealistic results may be obtained (wiggles, etc.). If *switch* is set to **-yes** results are stabilized with a minimal amount of artificial diffusion. If *switch* is set to **-maximal** results are stabilized with a maximal amount of artificial diffusion. If *switch* is set to **-no** results are not stabilized.

Default, if **convection\_stabilization** is not specified, *switch* is set to **-yes**.

#### 6.397 **data\_activate** *index data\_item\_name\_0 data\_item\_name\_1 ... switch*

With this record you can set data items to become activated if *switch* is set to **-yes** or de-activated if *switch* is set to **-no**. The *data\_item\_name* specifies a data record name.

#### 6.398 **data\_activate\_time** *index time*

Time point at which the record **data\_activate** with the same index is evaluated. If this record is not specified, the **data\_activate** is evaluated at the start of the calculation.

### 6.399 **data\_delete** *index data\_item\_name index\_range*

Similar to **control\_data\_delete**, but now not as control record however.

### 6.400 **data\_delete\_time** *index time*

Time point at which the record **data\_delete** with the same index is evaluated. If this record is not specified, the **data\_delete** is evaluated at the start of the calculation.

### 6.401 **data\_ignore** *data\_item\_name*

With this option Tochnog will ignore all data items with name *data\_item\_name*. This **data\_ignore** can also be set as environment symbol. As a typical example you can set the environment symbol **data\_ignore** to **-print\_apply**. Then when you run the tochnog example tests all **-print\_apply -no** in the tests will be ignored, so you get all printed output for the tests.

### 6.402 **dependency\_apply** *switch*

If *switch* is set to **-yes**, dependencies like specified in **dependency\_diagram** and **dependency\_item** are included in the calculation. If *switch* is set to **-no**, these dependencies are not included. This is done for all timestep records.

Default *switch* is set to **-yes**. See also **control\_dependency\_apply**.

### 6.403 **dependency\_diagram** *index dof\_value\_0 ... data\_item\_value\_0* ...

See **dependency\_item**.

### 6.404 **dependency\_method** *index method*

See **dependency\_item**.

### 6.405 **dependency\_geometry** *index geometry\_item\_name geometry\_item\_index*

See **dependency\_item**.

## 6.406 **dependency\_item** *index data\_item element\_group dof n*

This record allows you to make an element data item **group\_\*** dependent on one of the dof's, see **dof\_label** for dofnames, or on one of the post calculation results, see **post\_calcul\_label** for post calculation names. This is done for  $n$  values of the dof ( $n$  should be at least 2). The dependency should be specified in the **dependency\_diagram** record (same index) with a multi linear diagram. In the diagram first a set of dof's values should be specified. Second the set of data item values for those dof values should be specified. Please realise that the record which you want to make dependent needs to be specified itself also.

Some examples are given below.

Temperature dependent Young's modulus of element\_group 1 ( $E = 1.e10$  at temperature 1, etc.):

```
dependency_item 1 -group_materi_elasti_young 1 -temp 4  
dependency_diagram 1 1. 2. 3. 4. 1.e10 1.e9 1.e8 3.e5
```

Temperature dependent Young's moduli in two maxwell chains of element\_group 1 ( for the first chain the moduli  $1.e10, 1.e9, \dots$  for the second chain the moduli  $1.e12, 1.e11, \dots$  all relaxation times are  $1. 10^{-2}$ . ):

```
dependency_item 1 -group_materi_maxwell_chain 1 -temp 4  
dependency_diagram 1  
1. 2. 3. 4.  
1.e10 1.e9 1.e8 3.e5  
1.e-2 1.e-2 1.e-2 1.e-2  
1.e12 1.e11 1.e10 3.e7  
1.e-2 1.e-2 1.e-2 1.e-2
```

As a special option, *dof* can be set to **-time\_current**. This allows for time-dependent properties (aging). The example below shows time dependent Young's modulus of element\_group 1 ( $E = 1.e10$  at time 0, etc.):

```
dependency_item 1 -group_materi_elasti_young 1 -time_current 4  
dependency_diagram 1 0. 1. 2. 3. 1.e10 1.e9 1.e8 3.e5
```

As a special option, *element\_group* can be set to **-all**, so that the dependency diagram will be used for all groups.

As another special option, *dof* can be set to **-x**, **-y** or **-z**. This allows for dependency on one of the space coordinates. The example below shows a von-mises stress dependent on the z-coordinate for element\_group 1:

```
dependency_item 1 -group materi_plasti_vonmises 1 -z 4
dependency_diagram 1 -300. -200. -100. 0. 1.e5 1.e4 1.e3 1.e2
```

In 1D only **-x** can be used, in 2D only **-x** and **-y** can be used, and in 3D all of **-x**, **-y** and **-z** can be used.

The dependencies are available only for real precision data (and thus not for integer data). The **dependency\_diagram** values should be specified from low to high values for the dof.

The **dependency\_method** can be set to either **-use** or **-multiply**; with **-use** you specify that the values of **dependency\_diagram** will overwrite specified values for the data item; with **-multiply** you specify that the values of **dependency\_diagram** will multiply specified values for the data item; default, if **dependency\_method** is not specified, **-use** will be used.

With the **dependency\_type** record you can require that the cosinus, sinus or tangent of a data value is used in the dependency (in stead of the data value directly itself). The *type* can be set to either **-cosinus**, **-sinus** or **-tangent**. This is typically convenient for geotechnical safety factor calculations where you want that for a mohr coulomb law the cohesion and tangent of the friction angle are decreased at the same ratio in time. If you don't specify **dependency\_type** the value itself will be changed. To be clear we give the following four examples. If **dependency\_method** is set to **-use** and **dependency\_type** is not specified, then the value specified in the dependency diagram will be used for the data. If **dependency\_method** is set to **-use** and **dependency\_type** is set to **-tangent**, then the arc-tangent of the value specified in the dependency diagram will be used for the data. If **dependency\_method** is set to **-multiply** and **dependency\_type** is not specified, then the value specified in the dependency diagram will be multiplied with the original value for the data, and the result will be used as new value for for the data. If **dependency\_method** is set to **-multiply** and **dependency\_type** is set to **-tangent**, then the value specified in the dependency diagram will be multiplied with the tangent of the original value for the data, the arc-tangent of the result will be taken, and the final result will be used as new value for for the data.

With the **dependency\_number** record you can require that you only want to make one specific number of the data (0 for the first value, 1 for the second value, etc.) dependent. As a special option you can specify **-all** for the **dependency\_number** record, so that tochnog understands that you want to make all values in a record dependent. If you don't specify **dependency\_number** then all values of the record are made dependent.

The **dependency\_geometry** can be set to select a geometry for which the dependency is valid; outside the geometry the dependency will not be used; default, if **dependency\_geometry** is not specified, no geometry selection will be used.

The following gives as example lowering the tangent of the mohr coulomb friction angle with

a factor in time, for the elements of all groups within a radius distance from a point:

```
geometry_point 10 ...
...
dependency_item 1 -group_materi_plasti_mohr_coul -all-time_current
2
dependency_number 1 0 (only for the friction angle)
dependency_method 1 -multiply (use specified diagram as multiplication
factor)
dependency_type 1 -tangent (for the tangent, so not for the value itself)
dependency_diagram 1 10. 11. 1. 0. (lower the tangent of friction angle
between time 10 to time 11 from original value to 0)
dependency_geometry 1 -geometry_point 10 (do that only within a cer-
tain radius of a point)
```

You can use **print\_group\_data** to get the result for the calculated values using the dependency diagram. In fact, most **group\_\*** records can be used in the dependency diagram, but not all. Thus checking if things go like you want with the **print\_group\_data** is stringly advised.

#### 6.407 dependency\_number *index number*

See **dependency\_item**.

#### 6.408 dependency\_type *index type*

See **dependency\_item**.

#### 6.409 dof\_element\_dof *dof\_per\_element\_0 dof\_per\_element\_1 ...*

This record is for printing only. It is not meant as user input record. After the calculation the *dof\_per\_element\_0*, *dof\_per\_element\_1* etc. contain a **-yes** or **-no**. In case a dof is default calculated per element, so the field is non-continuous, a **-yes** is set. In case a dof is default calculated as continuous field a **-no** is set. This default calculation can be overruled by **global\_element\_dof\_apply**.

#### 6.410 dof\_label *dof\_0 dof\_1 ...*

This record will be filled with labels of the dof's in the correct order. This information is required for understanding records like **node\_dof** etc. The sequential order for the primary

dof's will match the order in which they are specified in the initialization part.

The total list of possible doflabels is:

- accx** acceleration in  $x$ -direction, -**accy**, -**accz**,
- cchis0**, -**cchis1** cam clay history variables,
- dam** damage,
- dens** density,
- dipriscohisv**, -**dipriscohis1**, ..., di prisco plasticity history variables,
- disx** displacement in  $x$ -direction, -**disy**, -**disz**,
- rdisx** relative displacement in  $x$ -direction, -**rdisy**, -**rdisz**,
- ener** material strain energy,
- epexx**  $xx$ -strain elastic, -**epexy**, -**epexz**, -**epeyy**, -**epeyz**, -**epezz**,
- epixx**  $xx$ -strain intergranular, -**epixy**, -**epixz**, -**epiyy**, -**epiyz**, -**epizz**,
- episa\_cxx**  $xx$ -strain isa intergranular, -**episa\_cxy**, -**episa\_cxz**, -**episa\_cyy**, -**episa\_cyz**,  
-**episa\_czz**,
- episa\_eacc** isa intergranular accumulated strain,
- eppxx**  $xx$ -strain plastic, -**eppxy**, -**eppxz**, -**eppyy**, -**eppyz**, -**eppzz**,
- eppcaxx**  $xx$ -strain plastic cap model, -**eppcaxy**, -**eppcaxz**, -**eppcayy**, -**eppcayz**, -  
-**eppcazz**,
- eppcoxx**  $xx$ -strain plastic compression model, -**eppcoxy**, -**eppcoxz**, -**eppcoyy**, -**eppcoyz**,  
-**eppcozz**,
- eppdixx**  $xx$ -strain plastic diprisco model, -**eppdixy**, -**eppdixz**, -**eppdiyy**, -**eppdiyz**,  
-**eppdizz**,
- eppdrxx**  $xx$ -strain plastic druckprag model, -**eppdrxy**, -**eppdrxz**, -**eppdryy**, -**eppdryz**,  
-**eppdrzz**,
- eppgencamxx**  $xx$ -strain plastic generalised non associate cam clay for bonded soils model,  
-**eppgencamxy**, -**eppgencamxz**, -**eppgencamy**, -**eppgencamyz**, -**eppgencamzz**,
- epphaxx**  $xx$ -strain plastic hardsoil model, -**epphaxy**, -**epphaxz**, -**epphayy**, -**epphayz**,  
-**epphazz**,

**-eppmoxx** *xx*-strain plastic mohr-coulomb model, **-eppmoxy**, **-eppmoxz**, **-eppmoyy**,  
**-eppmoyz**, **-eppmozz**,  
**-epptexx** *xx*-strain plastic tension model, **-epptexy**, **-epptexz**, **-eppteyy**, **-eppteyz**,  
**-epptezz**,  
**-eppvoxx** *xx*-strain plastic von-mises model, **-eppvoxy**, **-eppvoxz**, **-eppvoyy**, **-eppvoyz**,  
**-eppvozz**,  
**-eptxx** *xx*-strain total, **-eptxy**, **-eptxz**, **-eptyy**, **-eptyz**, **-eptzz**,  
**-f** plasticity yield rule,  
**-fn** nonlocal plasticity yield rule,  
**-fscal** time derivative of scalar,  
**-gvelx** ground water velocity in *x*-direction, **-gvely**, **-gvelz**.  
**-hisv0**, **-hisv1**, ..., material history variables,  
**-kap** plastic hardening parameter kappa,  
**-kapsh** shear plastic hardening parameter kappa,  
**-phimob** mobilized friction angle plasticity in degrees,  
**-pres** hydraulic pressure head,  
**-pres\_gradx** gradient hydraulic pressure head in *x* direction, **-pres\_grady**, **-pres\_gradz**  
**-rhoxx** *xx* plastic kinematic hardening, **-rhoxy**, **-rhoxz**, **-rhoxyy**, **-rhoxyz**, **-rhozz**,  
**-rotx** rotation around *x*-direction, **-roty**, **-rotz**,  
**-scal** scalar,  
**-sigxx** *xx*-stress, **-sigxy**, **-sigxz**, **-sigyy**, **-sigyz**, **-sigzz**,  
**-sigmkxx** *xx*-stress in the *k*-th maxwell chain, **-sigmkxy**, **-sigmkxz**, **-sigmkyy**, **-sigmkyz**,  
**-sigmkzz**,  
**-strtokap** total strain hardening parameter,  
**-strtocokap** compression part of total strain hardening parameter,  
**-strtoshkap** shear part of total strain hardening parameter,

**-strtotekap** tension part of total strain hardening parameter,

**-temp** temperature,

**-velx** velocity in  $x$ -direction, **-vely**, **-velz**,

**-velix** integrated velocity in  $x$ -direction, **-veliy**, **-veliz**,

**-void** material void fraction.

**-work** material second order work.

Furthermore, **-xvelx** denotes the spatial  $x$ -derivative of **-velx** in  $x$ -direction, etc.. Finally, **-tvelx** denotes the first time derivative of **-velx**, etc.. The time derivative and the space derivatives are only calculated if **derivatives** is included in the initialization part.

For example, the following might be seen after a print of the database

```
echo -yes
number_of_space_dimensions 2
derivatives
condif_temperature
end_initia
...
dof_label -temp -xtemp -ytemp -ttemp
...
```

Or, for example, the following might be seen after a print of the database

```
echo -yes
number_of_space_dimensions 2
condif_temperature
end_initia
...
dof_label -temp
...
```

#### 6.411 **dof\_limit** *lower\_dof\_0 upper\_dof\_0 lower\_dof\_1 upper\_dof\_1 ...*

With this record you can specify the lower and upper allowed values for all primary dof's. With *lower\_dof\_0* you specify the lower allowed value for the first dof. With *upper\_dof\_0*

you specify the upper allowed value for the first dof. Etc.

#### 6.412 **dtime** *dt*

This record contains after the calculation the last timestep used in the calculation. This record is meant for printing only.

#### 6.413 **element** *index element\_name node\_0 node\_1 node\_2 ...*

Nodal connective of element *index*. In 1D, *element\_name* is **-bar2** (2 noded bar), **-bar3**, **-bar4**. In 2D, *element\_name* is **-tria3** (3 noded triangle), **-tria6** (6 noded triangle), **-quad4** (4 noded quadrilateral), **-quad6** (6 noded quadrilateral, 2 sides of 3 nodes), **-quad8**, **-quad9**, **-quad16**. In 3D, *element\_name* is **-tet4** (4 noded tetrahedral), **-prism6** (6 noded prismatic), **-prism12** (12 noded prismatic), **-prism15** (15 noded prismatic), **-prism18** (18 noded prismatic), **-tet10** (10 noded tetrahedral), **-hex8** (8 noded hexahedral), **-hex18** (18 noded hexahedral, 2 sides of 9 nodes), **-hex20** (20 noded hexahedral, not formally available yet, still being tested, use with care), **-hex27**.

Further possibilities for *element\_name* are: **-spring2** (2 noded spring), **-contact\_spring1** (1 noded contact element), **-contact\_spring2** (2 noded contact element), the two nodes may have the same position in space. **-truss** (truss element), **-beam** (beam element), **-truss\_beam** (combined truss-beam element).

Some of the elements are drawn below.

See also: `group_type` and `group_integration_points`.

**6.414 element\_beam\_direction** *index dir\_x,x dir\_x,y dir\_x,z dir\_y,x*  
*dir\_y,y dir\_y,z dir\_z,x dir\_z,y dir\_z,z*

After the calculation, this record will be filled with the direction of a beam in space. The first three values give the direction of the local beam x direction, that is the beam torsion axis. The second three values give the direction of the local beam y direction, that is the beam y bending axis. The third three values give the direction of the local beam z direction, that is the beam z bending axis.

The *index* specifies the beam element number.

**6.415 element\_beam\_direction\_z** *index dir\_z,x dir\_z,y dir\_z,z*

The *index* specifies the beam element number.

Sate as **group\_beam\_direction\_z**, but now per element however.

**6.416 element\_beam\_force\_moment** *index force\_x\_first\_node force\_y\_first\_node force\_z\_first\_node moment\_x\_first\_node moment\_y\_first\_node moment\_z\_first\_node force\_x\_second\_node force\_y\_second\_node force\_z\_second\_node moment\_x\_second\_node moment\_y\_second\_node moment\_z\_second\_node ...*

After the calculation, this record will be filled with the forces and moments of a beam in the local beam axes  $x$ ,  $y$ ,  $z$ .

The *index* specifies the beam element number.

Attention: the values at the first node have a minus in their definition as compared with the values in the second node. For example in a beam number 20 with constant  $z$  moment of 10 you will find:

```
element_beam_force_moment 20 0. 0. 0. 0. 0. -10. 0. 0. 0. 0. 0. 10.
```

**6.417 element\_boundary** *index switch*

The *switch* will be set to **-yes** if the element with index *index* is located on the boundary of the mesh.

This record will only become available if **mesh\_boundary** is set to **-yes**. This record is meant for printing only, it should not be set by the user.

**6.418 element\_contact\_spring\_direction** *index dirN<sub>x</sub> dirN<sub>y</sub> dirN<sub>z</sub> dirT1<sub>x</sub> dirT1<sub>y</sub> dirT1<sub>z</sub> dirT2<sub>x</sub> dirT2<sub>y</sub> dirT2<sub>z</sub>*

In the input file, you can specify with this record the directions of a contact spring. If not specified, after the calculation this record will be filled with the used directions. The *index* specifies the spring element number.

#### 6.419 **element\_contact\_spring\_strain** *index strain\_N strain\_T1 strain\_T2*

After the calculation, this record will be filled with the normal and tangential elongation in a `contact_spring` element. The *index* specifies the spring element number. The tangential strain *strain\_T2* only is present in 3D.

#### 6.420 **element\_contact\_spring\_force** *index force\_N force\_T1 force\_T2*

After the calculation, this record will be filled with the normal and tangential forces in a `contact_spring` element. The *index* specifies the spring element number. The tangential force *force\_T2* only is present in 3D.

#### 6.421 **element\_dof** *index dof\_0 dof\_1 ...*

Unknowns as saved per element in the element nodes. First dof's in the first node. Then dof's in the second node. Etc.

This is done optionally by `tochnog`, only when needed for the calculation. The *index* specifies the element number.

#### 6.422 **element\_dof\_initial** *index dof\_0 dof\_1 ...*

When an element comes the first time to live, it assumes that it had in the past the dof's specified in this **element\_dof\_initial** record. You can either specify one value for each dof or you can specify values for the dof's for all nodes (specify first all dof's for the first node, then specify the dof's for the second node, etc.). The *index* specifies the element number.

This record will influence inertia terms (like mass acceleration, temperature capacity, etc). As an example you can set so the initial temperature of a part that is connected to the mesh at some time.

#### 6.423 **element\_dof\_initial\_specific\_number** *index number*

With this record you can an initial value for one specific dof. The *number* specifies the dof number, for example **-velx** or **-sigxx**, etc. The initial value for the dof needs to be specified with **element\_dof\_initial\_specific\_value**. The *index* specifies the element number.

#### 6.424 **element\_dof\_initial\_specific\_value** *index value\_0 value\_grad\_x value\_grad\_y value\_grad\_z*

This specifies for the **element\_dof\_initial\_specific\_number** record the initial value. Here *value\_0* is the value at coordinate  $x = y = z = 0$ , *value\_grad\_x* is the x-gradient, *value\_grad\_y* is the y-gradient and *value\_grad\_z* is the z-gradient. In 1D you only need to specify for the gradients the *value\_grad\_x* and in 2D you only need to specify for the gradients the *value\_grad\_x* and *value\_grad\_y*. As special option you can specify no gradients at all, and then a constant value in space of size *value\_0* will be used.

#### 6.425 **element\_empty** *index switch*

If Tochnog believes an element is empty, then it will set automatically *switch* to **-empty** for **element\_empty**.

#### 6.426 **element\_geometry** *index geometry\_set*

This data item specifies for element *index* a geometrical set number *geometry\_set*. Elements with the same geometrical set number together form a geometry, which can be referenced by functionality selecting elements by a geometry. The syntax for referring is **-element\_geometry geometry\_set**.

A typical application would be changing material data (groups) in time for different sets of elements. In the example below element 1 belongs to geometrical set 10. The elements of geometrical set 10 get in time respectively groups 100, 101, 102 and 103.

```

element 1 -bar2 1 2
element 2 -bar2 2 3
element_geometry 1 10
element_geometry 2 20
...
area_element_group_sequence_time 11 0. 1. 2. 3.
area_element_group_sequence_geometry 11 -element_geometry 10
area_element_group_sequence_element_group 11 100 101 102 103
...
area_element_group_sequence_time 12 0. 1. 2. 3.
area_element_group_sequence_geometry 12 -element_geometry 20
area_element_group_sequence_element_group 12 200 201 202 203
...

```

The **element\_geometry** cannot be used in a **geometry\_set**.

**6.427 element\_geometry\_present** *index geometry\_item\_name\_0 geometry\_item\_index\_0 geometry\_item\_name\_1 geometry\_item\_index\_1*  
...

This record lists for element *index* the geometries in which it is present. So it is a print record only, for checking if the geometries include exactly the elements that you want. You can switch on or off filling of these records by setting **print\_element\_geometry\_present** to **-yes** or **-no**.

**6.428 element\_group** *index element\_group*

This data item is specified which element data items should be taken for the element *index*. Example: elements 0 and 1 get density 1024 while element 2 gets density 1236

```

element 0 0 1 2
element 1 1 2 3
element 2 2 3 4
...
element_group 0 1
element_group 1 1
element_group 2 2
...
density 1 1024.
density 2 1236.

```

If no **element\_group** records are specified, all element data should use *index* is 0.

See also **area\_element\_group** and **element\_geometry**.

**6.429 element\_group\_apply** *index element\_group\_0 element\_group\_1*  
...

This is yet another option to change the group of elements. It works in combination with **control\_element\_group\_apply**. We explain it by means of an example:

```

element 43 ...
element 44 ...
...
element_group_apply 43 1 7 4
element_group_apply 44 21 22 8
...

```

```

control_element_group_apply 10 0 (element 43 gets group 1, element 44
gets group 21)
...
control_element_group_apply 20 2 (element 43 gets group 4, element 44
gets group 8)
...
control_element_group_apply 30 1 (element 43 gets group 7, element 44
gets group 22)
...

```

**6.430 element\_interface\_intpnt\_direction** *index normal\_x\_0 normal\_y\_0  
normal\_z\_0 first\_tangential\_x\_0 first\_tangential\_y\_0 first\_tangential\_z\_0  
second\_tangential\_x\_0 second\_tangential\_y\_0 second\_tangential\_z\_0*  
...

After the calculation this record will be filled with the direction vectors in interface element. Here *normal\_x\_0* is the x-component of the normal direction in the first integration point, etc.

**6.431 element\_interface\_intpnt\_gap\_status** *index status*

After the calculation, this record will be filled with the gap status in an interface element. The status is either **-opened** or **-closed**. The *index* specifies the interface element number.

**6.432 element\_interface\_intpnt\_materi\_tension\_status** *index status*

After the calculation, this record will be filled with the materi tension status in an interface element. The status is either **-opened** or **-closed**. The *index* specifies the interface element number.

**6.433 element\_interface\_intpnt\_strain** *index strain,normal,0 strain,shear,first,0  
strain,shear,second,0 strain,normal,1 strain,shear,first,1 strain,shear,second,1*  
...

After the calculation, this record will be filled with the normal strain, the first shear strain and second shear strain in the integration points of an an interface element. The values with subscript 0 are for the first integration point; The values with subscript 1 are for the second integration point; etc. For a 2D interface element the second shear strain will not be set.

In fact, the normal strain is the normal displacement difference, and the shear strains are half of the shear displacement differences.

This **element\_interface\_intpnt\_strain** record will only be filled if **materi\_strain\_total** is initialised. The *index* specifies the interface element number.

**6.434 element\_interface\_intpnt\_strain\_average** *index strain,normal,0 strain,shear,first,0 strain,shear,second,0*

Average of **element\_interface\_intpnt\_strain**.

**6.435 element\_interface\_intpnt\_stress** *index stress,normal,0 stress,shear,first,0 stress,shear,second,0 stress,normal,1 stress,shear,first,1 stress,shear,second,1 ...*

After the calculation, this record will be filled with the normal stress, the first shear stress and the second shear stress in the integration points of an interface element. The values with subscript 0 are for the first integration point; The values with subscript 1 are for the second integration point; etc. For a 2D interface element the second shear stress will not be set.

The *index* specifies the interface element number.

See **control\_reset\_interface** on how to reset strains and stresses somewhere in a calculation.

**6.436 element\_interface\_intpnt\_stress\_average** *index stress,normal,0 stress,shear,first,0 stress,shear,second,0*

Average of **element\_interface\_intpnt\_stress**.

**6.437 element\_intpnt\_dof** *index dof\_0 dof\_1 ...*

Unknowns as saved per element in the element integration points. The *index* specifies the element number.

**6.438 element\_intpnt\_h** *index ...*

This record is meant for printing only. It contains for each node of the element the value of the interpolation polynomial in the integration points.

**6.439 element\_intpnt\_iso\_coord** *index ...*

This record is meant for printing only. It contains for each node of the element the value of the isoparametric coordinates in the integration points.

**6.440 element\_intpnt\_materi\_plasti\_hardsoil\_gammap\_initial** *index gammap\_initial\_integration\_point\_0 gammap\_initial\_integration\_point\_1 ...*

See theory section on hardsoil.

**6.441 element\_intpnt\_materi\_undrained\_pressure** *index undrained\_total\_pressure*

Total pressure from undrained analysis. See **group\_materi\_undrained\_capacity**.

**6.442 element\_intpnt\_method** *index method*

This record is meant for printing only. It shows the space integration method that is actually used for element *index*. See also **group\_integration\_method**.

**6.443 element\_intpnt\_npoint** *index npoint*

This record is meant for printing only. It shows the number of space integration method points that are actually used for element *index*. See also **group\_integration\_points**.

**6.444 element\_middle** *index middle\_x middle\_y middle\_z*

After the calculation, this record will be filled with the middle coordinates of an element. The *index* specifies the element number.

**6.445 element\_normal** *index normal\_x normal\_y normal\_z*

This record will be generated in case it is needed during a calculation. It will contain the normal of an element in the inward normal direction of the mesh boundary. In 1d only *normal\_x* will be filled. In 2d only *normal\_x normal\_y* will be filled. In 3d all of *normal\_x normal\_y normal\_z* will be filled.

The side of an element is on the mesh boundary if no other element is connected to that side.

#### 6.446 **element\_print\_group\_data\_values** *index ...*

Values as required by **print\_group\_data**. The first value as required by **print\_group\_data** is placed in the first value of **element\_print\_group\_data\_values**. The second value as required by **print\_group\_data** is placed in the second value of **element\_print\_group\_data\_values**. Etc. Please realise that some group data requires more than one value, so that more than one value is filled in the **element\_print\_group\_data\_values** record.

#### 6.447 **element\_spring\_force** *index force*

After the calculation, this record will be filled with the force in a spring element. The *index* specifies the spring element number.

#### 6.448 **element\_spring\_strain** *index strain*

After the calculation, this record will be filled with the strain in a spring element. In fact the strain in a spring element is the elongation of the spring. The *index* specifies the spring element number.

In case you perform a geotechnical analysis and want to set all strains in the model to 0 after gravity has been imposed, then do a **control\_data\_delete** on all **element\_spring\_strain** records. In such way the **element\_spring\_strain** records will contain in the remaining part of the calculation strains relative to the gravity status.

#### 6.449 **element\_truss\_direction** *index dir\_x dir\_y dir\_z*

After the calculation, this record will be filled with the direction of a truss in space. The *index* specifies the truss element number.

#### 6.450 **element\_truss\_force** *index force*

After the calculation, this record will be filled with the normal force in a truss element. The *index* specifies the truss element number.

#### 6.451 **element\_truss\_strain** *index strain*

After the calculation, this record will be filled with the strain in a truss element (length increase divided by length). The *index* specifies the truss element number.

#### 6.452 **element\_truss\_strain\_temperature** *index strain*

After the calculation, this record will be filled with the normal thermal strain in a truss element (thermal length increase divided by length). The *index* specifies the truss element number.

#### 6.453 **element\_volume** *index volume*

This record contains the volume of the isoparametric element number *index* after the calculation. In fact for 1D elements it contains the element length, for 2D elements it contains the element area, and for 3D elements it contains the element volume.

#### 6.454 **force\_edge** *index force\_0 force\_1 ...*

Distributed edge forces. These distributed forces are translated into equivalent nodal force terms on the edges of elements. You should specify a force term for each direction. Also the record **force\_edge\_geometry** should be specified, and optionally the records **force\_edge\_factor**, **force\_edge\_multi\_linear\_factor\_x** and **force\_edge\_time** can be specified.

Attention: if this **force\_edge** option is used INSIDE a FE mesh, then the elements on each side of the geometry will get the force. So you may need to specify only half of the physical force value.

Attention: this option is only available for linear and quadratic isoparametric elements.

#### 6.455 **force\_edge\_diagram** *index vertical\_displacement\_0 factor\_0 vertical\_displacement\_1 factor\_1 ...*

This is a special purpose record, to make the specified forces dependent on vertical displacements. It actually contains multiplication factors for the force values as specified in the **force\_edge** record with the same index. You need to specify sets of vertical displacements and corresponding multiplication values. Please realise the following:

- In many geotechnical calculations vertical displacements are negative (so eg vertical\_displacement\_0 is -3.e-2, vertical\_displacement\_1 is -2.e-2 , etc.)
- The vertical displacements should be specified from low to high in the diagram.
- You need to specify all possible displacement values in the diagram.

#### 6.456 **force\_edge\_element** *index element\_0 element\_1 ...*

Selects the element for which the **force\_edge** record with the same *index* should be applied.

**6.457 force\_edge\_element\_group** *index element\_group\_0 element\_group\_1*  
 ...

Selects the element group for which the **force\_edge** record with the same *index* should be applied.

**6.458 force\_edge\_element\_node** *index element node\_0 node\_1 ...*

Selects the element and local node numbers for which the **force\_edge** record with the same *index* should be applied.

**6.459 force\_edge\_element\_side** *index element\_0 element\_1 ... side*

Selects the elements and local side number for which the **force\_edge** record with the same *index* should be applied.

**6.460 force\_edge\_factor** *index a\_0 a\_1 ... a\_n*

This data item defines a polynomial in space. This polynomial gives a factor which is used as a multiplication factor for **force\_edge** records (with the same index). In this way, you can obtain coordinate dependent forces.

In 1D the polynomial is  $a_0 + a_1x$  (specify 2 values). In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values). In 3D the polynomial is  $a_0 + a_1x + a_2y + a_3z$  (specify 4 values).

**6.461 force\_edge\_geometry** *index geometry\_entity\_name geometry\_entity\_index*

Selects the area for which the **force\_edge** record with the same *index* should be applied. For example, **-geometry\_line 1** can be used in 2D, indicating that the nodes on line 1 get the distributed force. The total edge of an element must be inside the geometry for the force to become active. For 2D elements the border lines are edges. For 3D elements the border surfaces are edges.

**6.462 force\_edge\_multi\_linear\_factor\_x** *index x\_0 factor\_0 x\_1 factor\_1 ...*

This factor is given as a multilinear diagram in x direction. This factor is used as a multiplication factor for **force\_edge** records (with the same index). In this way, you can obtain x-coordinate dependent forces. Outside the specified x-range the factor will be taken as 0.

**6.463 force\_edge\_node** *index node\_0 node\_1 ...*

Selects the nodes for which the **force\_edge** record with the same *index* should be applied. The *node\_0* etc. specify global node numbers.

**6.464 force\_edge\_node\_factor** *index factor\_0 factor\_1 ...*

Nodal multiplication factors with which the force of **force\_edge** will be applied to the nodes of **force\_edge\_node**. You need to specify a factor for each node. Here *factor\_0* is the multiplication factor for the first node, etc.

**6.465 force\_edge\_sine** *index start\_time end\_time freq\_0 amp\_0 freq\_1 amp\_1 ...*

The **force\_edge** record with the same *index* is imposed with the sum of the sine functions; the first sine function has frequency *freq\_0* and amplitude *amp\_0*, the second sine function has frequency *freq\_1* and amplitude *amp\_1*, etc.. The sine functions start at time 0. More general behavior in time can be imposed by using **force\_edge\_time** records. For a specific *index* only one of **force\_edge\_sine** and **force\_edge\_time** can be specified.

The sine loads will be only imposed after *start\_time*, and only up to *end\_time*.

More general time behavior can be specified with **force\_edge\_time**.

**6.466 force\_edge\_time** *index time load time load ...*

This record specifies a diagram which contains the factors with which the **force\_edge** record with the same *index* is applied. Linear interpolation is used to extend the *time load* values to the intervals between these pairs. Outside the specified time range a factor 0 is used.

If this record is not specified, and the **force\_edge\_sine** record is not specified, the force is applied at all times with a factor 1.

If no external forces like **force\_edge\_time** are specified, the internal element forces become zero at free edges to satisfy equilibrium. This causes, for example, temperature gradients to become zero at free edges in heat problems.

**6.467 force\_edge\_normal** *index force*

Distributed normal force in the direction of the outward normal at the edge of a element. This distributed term is translated into equivalent nodal force terms on the edges of elements.

Also the record **force\_\_edge\_\_normal\_\_geometry** should be specified, and optionally the record **force\_\_edge\_\_normal\_\_time** can be specified.

Attention: this option is only available for linear and quadratic isoparametric elements.

Attention: if this **force\_\_edge\_\_normal** option is used INSIDE a FE mesh, then the elements on each side will get the force. So the total force will normally become zero since the normals of the elements at the side of the geometry are opposite.

#### 6.468 **force\_\_edge\_\_normal\_\_element** *index element\_0 element\_1 ...*

Restricts the element to which the **force\_\_edge\_\_normal** record with the same *index* should be applied.

#### 6.469 **force\_\_edge\_\_normal\_\_element\_\_node** *index element node\_0 node\_1*

Selects the element and local node numbers for which the **force\_\_edge\_\_normal** record with the same *index* should be applied.

#### 6.470 **force\_\_edge\_\_normal\_\_element\_\_group** *index element\_group\_0 element\_group\_1 ...*

Restricts the element group to which the **force\_\_edge\_\_normal** record with the same *index* should be applied.

#### 6.471 **force\_\_edge\_\_normal\_\_element\_\_side** *index element\_0 element\_1 ... side*

Selects the elements and local side number for which the **force\_\_edge\_\_normal** record with the same *index* should be applied.

#### 6.472 **force\_\_edge\_\_normal\_\_factor** *index a\_0 a\_1 ... a\_{n-1}*

This data item defines a polynomial in space. This polynomial gives a factor which is used as a multiplication factor for **force\_\_edge\_\_normal** records (with the same index). In this way, you can obtain coordinate dependent forces.

In 1D the polynomial is  $a_0 + a_1x$  (specify 2 values). In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values). In 3D the polynomial is  $a_0 + a_1x + a_2y + a_3z$  (specify 4 values).

**6.473 force\_edge\_normal\_geometry** *index geometry\_entity\_name geometry\_entity\_index*

Selects the area for which the **force\_edge\_normal** record with the same *index* should be applied. For example, **-geometry\_line 1** can be used in 2D, indicating that the nodes on line 1 get the distributed force. The total edge of an element must be inside the geometry for the force to become active. For 2D elements the border lines are edges. For 3D elements the border surfaces are edges.

**6.474 force\_edge\_normal\_node** *index node\_0 node\_1 node\_2 ...*

Selects the nodes for which the **force\_edge\_normal** record with the same *index* should be applied. The *node\_0* etc. specify global node numbers.

**6.475 force\_edge\_normal\_node\_factor** *index factor\_0 factor\_1 ...*

Nodal multiplication factors with which the force of **force\_edge\_normal** will be applied to the nodes of **force\_edge\_normal\_node**. You need to specify a factor for each node. Here *factor\_0* is the multiplication factor for the first node on the side, etc.

**6.476 force\_edge\_normal\_sine** *index start\_time end\_time freq\_0 amp\_0 freq\_1 amp\_1 ...*

Same as **force\_edge\_sine**, now for normal edge loads however.

**6.477 force\_edge\_normal\_time** *index time load time load ...*

This record specifies a diagram which contains the factors with which the **force\_edge\_normal** record with the same *index* is applied. Linear interpolation is used to extend the *time load* values to the intervals between these pairs. Outside the specified time range a factor 0 is used.

If this record is not specified, the force is applied at all times with a factor 1.

**6.478 force\_edge\_projected** *index force ph(0,0,0) ph\_grad\_x ph\_grad\_y  
ph\_grad\_z  
pv(0,0,0) pv\_grad\_x pv\_grad\_y pv\_grad\_z factor\_normal factor\_tangential  
vertical\_dir\_downward\_x vertical\_dir\_downward\_y vertical\_dir\_downward\_z  
tunnel\_dir\_x tunnel\_dir\_y tunnel\_z*

Distributed projected force on the edge of a element. This distributed term is translated into equivalent nodal force terms on the edges of elements.

This record typically can be used to model soil normal and tangential loading on tunnels. With `ph(0,0,0)` you specify the horizontal ground stress at  $x=0, y=0, z=0$ . With `ph_grad_x`, `ph_grad_y` and `ph_grad_z` you specify the gradients of the horizontal stress (such that a linear horizontal stress field can be modeled). With `pv(0,0,0)` you specify the vertical ground stress at  $x=0, y=0, z=0$ . With `pv_grad_x`, `pv_grad_y` and `pv_grad_z` you specify the gradients of the vertical stress (such that a linear vertical stress field can be modeled).

The vertical and horizontal stresses are projected on the edge of the element so that the radial stress `sig_radial` and the tangential stress `sig_tangential` of the edge of the element are obtained. You can decide to apply the radial stress `sig_radial` only with a factor `factor_normal` (between 0 and 1). Likewise, you can decide to apply the tangential shear stress `sig_tangential` only with a factor `factor_tangential` (between 0 and 1).

As extra information for Tochnog to determine the correct radial stress and tangential shear stress on the edge of an element you need to specify the downward vertical direction with `vertical_dir_downward_x`, `vertical_dir_downward_y` and `vertical_dir_downward_z`.

Only in 3D, you also need to specify the length direction of the tunnel axis with `tunnel_dir_x`, `tunnel_dir_y` and `tunnel_z`.

In 2D you should not specify the 3D information `ph_grad_z`, `pv_grad_z`, `vertical_dir_downward_z`, `tunnel_dir_x`, `tunnel_dir_y` and `tunnel_z`.

Also the record **force\_edge\_projected\_geometry** should be used to specify where the force should be applied, and optionally the record **force\_edge\_projected\_time** can be specified.

Attention: notice that horizontal soil stress in length direction of the tunnel is not included.

Attention: this option is only available for linear and quadratic isoparametric elements.

Attention: if this **force\_edge\_projected** option is used INSIDE a FE mesh, then the elements on each side will get the force. So the total force will protectedly become zero since the projected of the elements at the side of the geometry are opposite.

**6.479 force\_edge\_projected\_element** *index element\_0 element\_1 ...*

Restricts the element to which the **force\_edge\_projected** record with the same *index* should be applied.

**6.480 force\_edge\_projected\_element\_node** *index element node\_0 node\_1 ...*

Selects the element and local nodes for which the **force\_edge\_projected** record with the same *index* should be applied.

**6.481 force\_edge\_projected\_element\_group** *index element\_group\_0 element\_group\_1 ...*

Restricts the element group to which the **force\_edge\_projected** record with the same *index* should be applied.

**6.482 force\_edge\_projected\_element\_side** *index element\_0 element\_1 ... side*

Selects the elements and local side number for which the **force\_edge\_projected** record with the same *index* should be applied.

**6.483 force\_edge\_projected\_factor** *index a\_0 a\_1 ... a\_n*

This data item defines a polynomial in space. This polynomial gives a factor which is used as a multiplication factor for **force\_edge\_projected** records (with the same index). In this way, you can obtain coordinate dependent forces.

In 1D the polynomial is  $a_0 + a_1x$  (specify 2 values). In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values). In 3D the polynomial is  $a_0 + a_1x + a_2y + a_3z$  (specify 4 values).

**6.484 force\_edge\_projected\_geometry** *index geometry\_entity\_name geometry\_entity\_index*

Selects the area for which the **force\_edge\_projected** record with the same *index* should be applied. For example, **-geometry\_line 1** can be used in 2D, indicating that the nodes on line 1 get the distributed force. The total edge of an element must be inside the geometry for the force to become active. For 2D elements the border lines are edges. For 3D elements the border surfaces are edges.

**6.485 force\_edge\_projected\_node** *index node\_0 node\_1 node\_2 ...*

Selects the nodes for which the **force\_edge\_projected** record with the same *index* should be applied. The *node\_0* etc. specify global node numbers.

**6.486 force\_edge\_projected\_node\_factor** *index factor<sub>0</sub> factor<sub>1</sub> ...*

Nodal multiplication factors with which the force of **force\_edge\_projected** will be applied to the nodes of **force\_edge\_projected\_node**. You need to specify a factor for each node. Here *factor<sub>0</sub>* is the multiplication factor for the first node, etc.

**6.487 force\_edge\_projected\_sine** *index start\_time end\_time freq\_0  
amp\_0 freq\_1 amp\_1 ...*

Similar to **force\_edge\_sine**, now for projected edge loads however.

**6.488 force\_edge\_projected\_time** *index time load time load ...*

This record specifies a diagram which contains the factors with which the **force\_edge\_projected** record with the same *index* is applied. Linear interpolation is used to extend the *time load* values to the intervals between these pairs. Outside the specified time range a factor 0 is used.

If this record is not specified, the force is applied at all times with a factor 1.

**6.489 force\_edge\_water** *index switch*

If *switch* is set to **-yes**, distributed water pressure force is added to the model. This distributed term is translated into equivalent nodal force terms on the edges of elements. The distributed force is automatically calculated as  $\text{density\_water} \cdot g \cdot \Delta z$  where  $g$  is the gravitational acceleration, and  $\Delta z$  is the distance to the phreatic level. The water pressure force acts normal to the element edge, in inward direction. You need to specify also **force\_edge\_water\_geometry**.

The water density is given by **groundflow\_density**. The gravity acceleration is given by the vertical component of **force\_gravity**. The water height is relative to the water height is given by **groundflow\_phreatic\_level**.

Attention: if this **force\_edge\_water** option should be used with care INSIDE a FE mesh.

The total edge of an element must be inside the geometry for the force to become active. For 2D elements the border lines are edges. For 3D elements the border surfaces are edges.

**6.490 force\_edge\_water\_element** *index element\_0 ...*

Selects the element for which the **force\_edge\_water** record with the same *index* should be applied.

**6.491 force\_edge\_water\_element\_group** *index element\_group\_0 ...*

Selects the element groups for which the **force\_edge\_water** record with the same *index* should be applied.

**6.492 force\_edge\_water\_element\_node** *index element node\_0 node\_1 ...*

Selects the element and local nodes for which the **force\_edge\_water** record with the same *index* should be applied.

**6.493 force\_edge\_water\_element\_side** *index element\_0 element\_1 ... side*

Selects the elements and local side number for which the **force\_edge\_water** record with the same *index* should be applied.

**6.494 force\_edge\_water\_factor** *index a\_0 a\_1 ... a\_n*

This data item defines a polynomial in space. This polynomial gives a factor which is used as a multiplication factor for **force\_edge\_water** records (with the same index). In this way, you can obtain coordinate dependent forces.

In 1D the polynomial is  $a_0 + a_1x$  (specify 2 values). In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values). In 3D the polynomial is  $a_0 + a_1x + a_2y + a_3z$  (specify 4 values).

**6.495 force\_edge\_water\_geometry** *index geometry\_item\_name geometry\_item\_index*

Selects the area for which the **force\_edge\_water** record with the same *index* should be applied. For example, **-geometry\_line 1** can be used in 2D, indicating that the nodes on line 1 get the distributed water pressure force.

**6.496 force\_edge\_water\_node** *index node\_0 node\_1 ...*

Selects the nodes for which the **force\_edge\_water** record with the same *index* should be applied. The *node\_0* etc. specify global node numbers.

**6.497 force\_edge\_water\_time** *index time load time load ...*

This record specifies a diagram which contains the factors with which the **force\_edge\_water** record with the same *index* is applied. Linear interpolation is used to extend the *time load* values to the intervals between these pairs. Outside the specified time range a factor 0 is used.

If this record is not specified, the force is applied at all times with a factor 1.

**6.498 force\_gravity** *g\_x g\_y g\_z*

Gravitational acceleration.

In 1D, only the gravity in x-direction needs to be specified. In 2D, the gravity in x-direction and y-direction needs to be specified. In 3D, the gravity in x-direction, y-direction and z-direction needs to be specified.

See also **force\_gravity\_time**.

**6.499 force\_gravity\_geometry** *geometry\_item\_name geometry\_item\_index*

With this record you can specify a geometrical entity on which the gravity force should be used. Only elements inside the geometry get the gravity force.

If this record is not specified all elements can get the gravity force.

See also **force\_gravity\_time**.

**6.500 force\_gravity\_time** *time load time load ...*

This record specifies a multi-linear diagram which contains the factors with which the **force\_gravity** record is applied. This allows you to impose the gravity on a structure slowly, which might be needed for path dependent problems. Outside the specified time range a factor 0 is used.

If this record is not specified, the gravity is applied at all times with a factor 1.

### 6.501 **force\_point** *index coord\_0 coord\_1 coord\_2 force\_0 force\_1 force\_2*

Point force in space; it needs not to be exactly in a node. The force will be distributed over the element nodes in which the point force is located. This will be done consistent with the element interpolation functions (linear or quadratic).

The *coord\_0* specifies the x-coordinate in space. The *coord\_1* specifies the y-coordinate in space (only in two or 3 dimensions). The *coord\_2* specifies the z-coordinate in space (only in 3 dimensions). The *force\_0* specifies the x-force in space. The *force\_1* specifies the y-force in space (only in two or 3 dimensions). The *force\_2* specifies the z-force in space (only in 3 dimensions).

You can use the usual **change\_dataitem\_time** to change the position (or value) of the point force in time.

### 6.502 **force\_volume** *index force\_0 force\_1 ...*

Distributed volume forces for each direction. Here *force\_0* is the distributed force in the x-direction, etc. Consider the example with distributed volume force in x-direction for a 2D material:

```
force_volume 0 1.0.
```

The **force\_volume** record can be used in **dependency\_diagram** records (just like element group data)/

See also **force\_volume\_factor**, **force\_volume\_geometry**, and **force\_volume\_time**.

### 6.503 **force\_volume\_element** *index element\_0 element\_1 ...*

Specifies the elements for which the **force\_volume** record with the same *index* should be applied.

### 6.504 **force\_volume\_element\_group\_0** *element\_group\_1 ... index element\_group*

Specifies the element group for which the **force\_volume** record with the same *index* should be applied.

#### 6.505 **force\_volume\_factor** *index a<sub>0</sub> a<sub>1</sub> ... a<sub>n</sub>*

This polynomial gives a factor which is used as a multiplication factor for **force\_volume** records (with the same index). In this way, you can obtain coordinate dependent forces.

In 1D the polynomial is  $a_0 + a_1x$  (specify 2 values). In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values). In 3D the polynomial is  $a_0 + a_1x + a_2y + a_3z$  (specify 4 values).

#### 6.506 **force\_volume\_geometry** *index geometry\_item\_name geometry\_item\_index*

Specifies the area for which the **force\_volume** record with the same *index* should be applied. For example, **-geometry\_quadrilateral 1** can be used in 2D, indicating that the elements on quadrilateral 1 get the distributed force.

If both the **force\_volume\_element** and **force\_volume\_geometry** are not specified, then a geometry which encloses the whole model will be applied.

#### 6.507 **force\_volume\_sine** *index start\_time freq\_0 amp\_0 freq\_1 amp\_1 ...*

Same as **force\_volume\_sine**, now for volume loads however.

#### 6.508 **force\_volume\_time** *index time load time load ...*

This record specifies a multi-linear diagram which contains the factors with which the **force\_volume** record with the same index is applied.

If this record is not specified, the force is applied at all times with a factor 1.

#### 6.509 **geometry\_boundary** *index switch*

With this record you can restrict a geometry to the boundary of the mesh, or to the inside of the mesh. If *switch* is set to **-yes** only nodes which are at the boundary of the mesh are actually used for the geometry with the same index. If *switch* is set to **-no** only nodes which are not at the boundary of the mesh are actually used for the geometry with the same index.

Attention: for this option to work correctly, the mesh should not contain badly shaped elements. See the section at the end of this manual for more information on bad element shapes.

#### 6.510 **geometry\_\_bounda\_\_sine\_\_x** *index a b*

This sets, for the geometrical entity with the same index an extra factor which is used for the **bounda\_\_dof** and the **bounda\_\_force** records. The factor gives a sinus variation in x-direction. The size of the factor is  $\sin(a + b * x)$ .

#### 6.511 **geometry\_\_bounda\_\_sine\_\_y** *index a b*

This sets, for the geometrical entity with the same index an extra factor which is used for the **bounda\_\_dof** and the **bounda\_\_force** records. The factor gives a sinus variation in y-direction. The size of the factor is  $\sin(a + b * y)$ .

#### 6.512 **geometry\_\_bounda\_\_sine\_\_z** *index a b*

This sets, for the geometrical entity with the same index an extra factor which is used for the **bounda\_\_dof** and the **bounda\_\_force** records. The factor gives a sinus variation in z-direction. The size of the factor is  $\sin(a + b * z)$ .

#### 6.513 **geometry\_\_brick** *index x\_c y\_c z\_c l\_x l\_y l\_z tolerance*

This data item defines a brick in space. Other data items can check if nodes are located on this geometry. The coordinate of the center is  $x_c y_c z_c$ . The length in respectively  $x$ ,  $y$  and  $z$  direction are  $l_x l_y l_z$ . All **node** within a distance *tolerance* are considered to be part of the brick.

#### 6.514 **geometry\_\_circle** *index x\_c y\_c ... radius tolerance*

This data item defines a circle in space. Other data items can check if nodes are located on this geometry. The coordinate of the center is  $x_c y_c$ . In 2D you need to specify  $x_c y_c radius tolerance$ . In 2D all **node** within a distance *tolerance* of the radius are considered to be part of the circle. In 3D you need to specify  $x_c y_c z_c normal_x normal_y normal_z radius tolerance$ , where  $normal_x normal_y normal_z$  specifies the direction normal to the surface. In 3D all **node** within a distance *tolerance* of the circle surface are considered to be part of the circle.

#### 6.515 **geometry\_\_circle\_\_part** *index x\_c y\_c angle\_start angle\_end radius tolerance*

This data item defines a circle in 2D space. Other data items can check if nodes are located on this geometry. The coordinate of the center is  $x_c y_c$ . All **node** within a distance

*tolerance* of the radius are considered to be part of the circle. The circle part starts at angle *angle\_start*, measured in radians from the positive x-axis. The circle part ends at angle *angle\_end*, measured in radians from the positive x-axis.

**6.516 geometry\_circle\_segment** *index x\_c y\_c radius side\_x side\_y tolerance*

This data item defines a circle segment in space. Other data items can check if nodes are located on this geometry. The coordinate of the center is *x\_c y\_c*. If *side\_x* is set to a positive value, say +1., then only x-values larger than *x\_c* are considered to be part of the geometry. If *side\_x* is set to a negative value, say -1., then only x-values smaller than *x\_c* are considered to be part of the geometry. If *side\_x* is set to 0, then all x-values are considered to be part of the geometry. Likewise remarks hold for y-values. All **node** within a distance *tolerance* of the radius are considered to be part of the circle segment.

**6.517 geometry\_cylinder** *index x\_0 y\_0 z\_0 x\_1 y\_1 z\_1 radius tolerance*

This data item defines a cylinder segment in space. Other data items can check if nodes are located on this geometry. The coordinate of the center point at the bottom is *x\_0 y\_0 z\_0*. The coordinate of the center point at the top is *x\_1 y\_1 z\_1*. The cylinder can only be used in 3D. All **node** within a distance *tolerance* of the radius are considered to be part of the cylinder.

**6.518 geometry\_cylinder\_part** *index x\_0 y\_0 z\_0 x\_1 y\_1 z\_1 radius angle\_start\_0 angle\_end\_0 angle\_start\_1 angle\_end\_1 ... tolerance*

This data item defines parts of a cylinder in space. Other data items can check if nodes are located on this geometry.

The *index x\_0 y\_0 z\_0 x\_1 y\_1 z\_1 radius* are the same as in **geometry\_cylinder**.

The *angle\_start\_0 angle\_end\_0* defines the first valid part of the cylinder, where *angle\_start\_0* is the start angle of the part and *angle\_end\_0* is the end angle. The angles are measured in the x-y plane, starting from the positive x-axis towards the positive y-axis. Likewise, the *angle\_start\_1 angle\_end\_1* defines a second valid part of the cylinder. You should define at least one valid part, and optionally you can specify several valid parts.

Start angles and end angles should be non-negative. End angles should be larger than start angles.

Angles will be measured relative to the vector as specified in **geometry\_cylinder\_part\_start\_vector**, if that vector is specified. This **geometry\_cylinder\_part\_start\_vector** should be specified perpendicular to the cylinder axes. This **geometry\_cylinder\_part\_start\_vector**

should be exactly in the middle of the angle range that you want to select. With **geometry\_cylinder\_part\_start\_vector** only one angle range is allowed, and the start angle should be 0. All nodes with an angle smaller or equal to the end angle are accepted as valid (thus, you get a total angle range of twice the end angle size as valid range).

If **geometry\_cylinder\_part\_start\_vector** is not specified, the **geometry\_cylinder\_part** should be either along the x-direction, y-direction or z-direction; then the angle is measured relative to the axes (for example for a cylinder along the z-direction the angle starts at the x-axes).

All **node** within a distance *tolerance* of the radius and inside a valid part are considered to be part of the cylinder part.

**6.519 geometry\_cylinder\_part\_start\_vector** *index v\_x v\_y v\_z*

See **geometry\_cylinder\_part**.

**6.520 geometry\_cylinder\_segment** *index x\_0 y\_0 z\_0 x\_1 y\_1 z\_1  
radius side\_x side\_y side\_z tolerance*

This data item defines a cylindrical segment in space. Other data items can check if nodes are located on this geometry. The coordinate of the center point at the bottom is *x\_0 y\_0 z\_0*. The coordinate of the center point at the top is *x\_1 y\_1 z\_1*. If *side\_x* is set to a positive value, say +1., then only x-values larger than *x\_c* are considered to be part of the geometry. If *side\_y* is set to a negative value, say -1., then only x-values smaller than *x\_c* are considered to be part of the geometry. If *side\_x* is set to 0, then all x-values are considered to be part of the geometry. Likewise remarks hold for y- and z-values. The cylinder segment can only be used in 3D. All **node** within a distance *tolerance* of the radius are considered to be part of the cylinder.

**6.521 geometry\_exclude** *index geometry\_item\_name\_0 geometry\_item\_index\_0  
geometry\_item\_name\_1 geometry\_item\_index\_1 ...*

With this record you can exclude geometries from the geometry with the same index. The next 2D example excludes a circular area with radius 0.3 inside a quadrilateral:

```
...
geometry_quadrilateral 10 0. 0. 1. 0. 0. 1. 1. 1.
geometry_exclude 10 -geometry_point 20

geometry_point 20 0.5 0.5 0.3
...
```

You are not allowed to let a **geometry\_\*** use a **geometry\_exclude** which contains itself.

**6.522 geometry\_element\_geometry** *index element\_geometry\_0 element\_geometry\_1*  
...

Similar to **geometry\_element\_group**, but now using **element\_geometry** i.s.o. **element\_group** however.

**6.523 geometry\_element\_geometry\_method** *index method*

Similar to **geometry\_element\_group\_method**.

**6.524 geometry\_element\_group** *index element\_group\_0 element\_group\_1*  
...

With this record you can restrict the geometry as specified in the geometry record with the same *index*. For example for the geometry as specified by

```
...
geometry_quadrilateral 10 ...
geometry_element_group 10 ...
...
```

nodes which are located on the **geometry\_quadrilateral 10**, but at the same time are also a node of elements of one of the specified element groups *element\_group\_0 element\_group\_1* etc., belong to the geometry. Nodes which are not a node of elements of one of the groups do not belong to the geometry, even if such nodes are located on the **geometry\_quadrilateral 10**.

See also **geometry\_element\_group\_method**.

**6.525 geometry\_element\_group\_method** *index method*

With this record you can set the *method* that the **geometry\_element\_group** record uses. If *method* is set to **-all** then a node should be attached to all the specified element groups, to be part of the geometry. If *method* is set to **-any** then a node should be attached to any of the specified element groups, to be part of the geometry. If *method* is set to **-only** then a node should be attached to only the specified element groups, to be part of the geometry. Default, if *method* is not specified then **-any** is assumed.

### 6.526 **geometry\_ellipse** *index x\_c y\_c a b tolerance*

The coordinate of the center is  $x_c$   $y_c$ . The equation for the ellipse is:

$$\left(\frac{x-x_c}{a}\right)^2 + \left(\frac{y-y_c}{b}\right)^2 = 1$$

Other data items can check if nodes are located on this geometry. The ellipse can only be used in 2D. All **node** within a distance *tolerance* of the ellipse are considered to be part of the ellipse.

### 6.527 **geometry\_factor** *index factor\_0 ...*

This sets for some geometries extra factors which are used for the **bounda\_dof**, **bounda\_force** and **force\_edge\_\*** records. For a **geometry\_line** either 2 or 3 factors should be specified; 2 factors define a linear variation where the factors hold at the start and end of the line respectively; 3 factors define a parabolic variation where the factors hold at the start, at the middle and at the end of the line respectively. For a **geometry\_triangle** 3 factors should be specified (a linear variation with factors for the first, second and third corner point respectively). For a **geometry\_quadrilateral** 4 factors should be specified (a linear variation with factors for the first, second, third and fourth corner point respectively). For a **geometry\_point** 1 factor should be specified; a multiplication with a half sine wave will be used, with the specified factor in the middle (exactly at the point) creasing to factor 0 at a distance *tolerance* from the point,

In the example below, node 2 will get temperature  $20 * 1.6$  and node 3 will get temperature  $20 * 2.2$ .

```
...
number_of_space_dimensions 2
condif_temperature
...
end_initia
node 2 0.2 0
node 3 0.4 0.
...
geometry_line 1 0. 0. 1. 0. 0.01
geometry_factor 1 1. 4.
bounda_dof 0 -geometry_line 1 -temp
bounda_time 0 0. 20. 1.e6 20.
...
end_data
```

**6.528 geometry\_hexahedral** *index*  $x\_0\ y\_0\ z\_0\ x\_1\ y\_1\ z\_1\ x\_2\ y\_2\ z\_2\ x\_3\ y\_3\ z\_3\ x\_4\ y\_4\ z\_4\ x\_5\ y\_5\ z\_5\ x\_6\ y\_6\ z\_6\ x\_7\ y\_7\ z\_7$

This data item defines a hexahedral in space. Other data items can check if nodes are located on this geometry (everything inside the hexahedral belongs to the geometry). The coordinates of the corner points are  $x\_0\ y\_0\ z\_0$  etc.. The points of the hexahedral should be specified in the correct order; the order is clarified in the example below.

Example

```
...
number_of_space_dimensions 3
...
geometry_hexahedral 0 0. 0. 0. 1. 0. 0. 0. 1. 0. 1. 1. 0. 0. 0. 1. 1.
0. 1. 0. 1. 1. 1. 1. 1.
...
```

Notice the order in which the points are to be specified.

**6.529 geometry\_line** *index*  $x\_0\ y\_0\ z\_0\ x\_1\ y\_1\ z\_1$  *radius*

This data item defines a line in space. Other data items can check if nodes are located on this geometry. Coordinates of the end points are denoted by  $x\_0$ , etc.. In 1D, only the  $x$ -coordinates should be specified, etc.. All **node** within a distance *radius* are considered to be part of the line.

In the example, a line in 2D space is defined and is used by a **convection\_geometry** record (nodes located on the line will convect heat)

```
...
geometry_line 2 1. 0. 1. 1. 0.01
...
group_condif_convection_edge_normal_geometry 0-geometry_line
2
...
```

**6.530 geometry\_line\_eps\_iso** *index* *iso\_tolerance*

With this parameter you can ask Tochnog to accept points just outside the line in direction of the line. Typically try  $1.e-3$  for *iso\_tolerance*.

### 6.531 **geometry\_list** *index number\_0 number\_1 ...*

This is a list of numbers which can be used in geometry selection options.

For example

```
...
geometry_list 10 1 45 43 26 27
...
bounda_dof 200 -geometry_list 10 ... (set the boundary condition on the
nodes of the list)
...
```

### 6.532 **geometry\_method** *index method*

For selecting elements with a geometry entity you can set the *method* either to **-all**, **-any** or **-average**. With **-all** all nodes of an element should be inside the geometry entity for the element to be selected (completely inside). With **-any** any node of an element should be inside the geometry entity for the element to be selected (at least partially inside). With **-average** the middle coordinate of an element should be inside the geometry entity for the element to be selected. Default if this record is not specified the *method* is set to **-all**.

### 6.533 **geometry\_moving** *index geometry\_entity*

This option comes handy when you want to model moving excavations in complex FE meshes. For complex geological regions it is not possible to make the FE mesh a priori in such way that the excavation zones can be easily defined in terms of element groups or otherwise. In such case this option allows geometrical entities to move through the complex FE mesh. The geometrical entity will determine automatically which elements become part of the entity at which times, and then will automatically excavate those elements. Elements which are at a moment in time only partly inside the geometrical entity, will be only partly excavated to the same amount as which they are inside the geometrical entity. Elements which are at a moment in time completely inside the geometrical entity, will be fully excavated.

We first explain the usage of this option by means of an example:

```
...
geometry_moving 10 -geometry_point (geometrical point that will move
in space and excavate the mesh)
geometry_moving_parameter 10 -1. -1. 2.e-1 (start x-coordinate of
```

```

point, start y-coordinate of point, radius of point)
geometry_moving_operat 10 -translate (translate the point in space)
geometry_moving_operat_parameter 10 1. 1. (velocity of point in x-
direction, velocity of point in y-direction)
geometry_moving_operat_time 10 0. 3. (start time of point moving,
end time of point moving)
geometry_moving_n 10 200 200 (number of time discretisation, number of
space distretisation)
...
mesh_delete_geometry_moving 10 10 (tell Tochnog to use the geome-
try_moving records with index 10 to excavate the mesh)
...
control_geometry_moving 25 -initialise (prepare the point for moving
through the mesh)
...
control_timestep 30 ...
...

```

The geometrical entity can be one of **-geometry\_point**, **-geometry\_triangle**, **-geometry\_quadrilateral**, **-geometry\_hexahedral** and **-geometry\_tetrahedral**.

#### 6.534 **geometry\_moving\_parameter** *index parameters of entity*

For each vertex of the geometry you need to specify the initial x-coordinate, y-coordinate (only for 2D and 3D) and z-coordinate. A point has one vertex, a triangle three, a quadrilateral four, a hexahedral eight and a tetrahedral six. The sequence of the vertices is the same as the sequence of nodes for the similar finite elements (see **element**). For a **-geometry\_point** you need to specify additionally the radius.

See also **geometry\_moving**.

#### 6.535 **geometry\_moving\_operat** *index operator*

This *operator* specifies how the geometry changes between *time\_start* and *time\_end*. If *operator* is set to **-translate** the geometry moves in space with a constant velocity vector.

See also **geometry\_moving**.

### 6.536 **geometry\_moving\_operat\_parameter** *index parameters of operator*

For a **-translate** you need to specify the x-velocity, y-velocity (only for 2D and 3D) and z-velocity.

See also **geometry\_moving**.

### 6.537 **geometry\_moving\_operat\_time** *index start\_time end\_time*

The *start\_time* specifies when the geometry comes into existence and starts to move. The *end\_time* specifies when the geometry stops moving but remains in existence.

See also **geometry\_moving**.

### 6.538 **geometry\_moving\_n** *index ntime nspace*

The **geometry\_moving** command needs to find out for each element at each time point which part of the element is part of the geometrical entity. In order to found this out, it is checked for many points inside each element if the point is inside the geometrical entity. In fact, for a 1D element *nspace* points will be used, for a 2D element *nspace* \* *nspace* points will be used and for *nspace* \* *nspace* \* *nspace* points will be used.

This checking which part of each element is inside the geometrical entity will be done at *ntime* time moments between *time\_start* and *time\_end*.

Default, if **geometry\_moving** is not specified, we use *ntime* is 100 and *nspace* is 5.

See also **geometry\_moving**.

### 6.539 **geometry\_mpc** *index switch*

With this record you can restrict the geometry as specified in the geometry record with the same *index*. Only nodes which have mpc's are considered to be part of the geometry.

### 6.540 **geometry\_node\_type** *node\_type*

If *node\_type* is set to **-node\_start\_refined** the values of **-node\_start\_refined** are used for evaluating the geometry. If *node\_type* is set to **-node** the values of **-node** are used for evaluating the geometry. If *node\_type* is set to **-plus\_displacement** the values of **-node** plus nodal displacements are used for evaluating the geometry. Default *node\_type* is set to **-node\_start\_refined**.

#### 6.541 **geometry\_point** *index x y z radius*

This data item defines a point in space. Other data items can check if nodes are located on this geometry. The coordinate of the point is  $x\ y\ z$ . In 1D, only  $x$  should be specified, etc.. All **node** within a distance *radius* are considered to be part of the point.

#### 6.542 **geometry\_polynomial** *index $a_0\ a_1\ \dots\ a_n\ x\_0\ x\_1\ y\_0\ y\_1\ tolerance$*

This data item defines a polynomial in space in 2D or 3D. Other data items can check if nodes are located on this geometry.

In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values). In 3D the polynomial is  $a_0 + a_1x + a_2y + a_3z$  (specify 4 values).

In 2D  $x_0 - x_1$  defines the domain of  $x$ . In 3D  $x_0 - x_1$  defines the domain of  $x$  and  $y_0 - y_1$  defines the domain of  $y$ . All **node** with a distance (that is the  $y$ -distance in 2D or the  $z$ -distance in 3D) not more than *tolerance* are considered to be part of the polynomial.

#### 6.543 **geometry\_projection\_type** *index type*

This record allows you to control what geometry will actually be used. Set *type* to **-project\_inside** or **-project\_exact**. For example if the geometry is a **geometry\_circle** then **-project\_inside** means that everything inside the circle will be used, whereas **-project\_exact** means that everything within a tolerance from the circle edge will be used. Default *type* is **-project\_exact**.

#### 6.544 **geometry\_quadrilateral** *index $x\_0\ y\_0\ z\_0\ x\_1\ y\_1\ z\_1\ x\_2\ y\_2\ z\_2\ x\_3\ y\_3\ z\_3\ tolerance$*

This data item defines a quadrilateral in space. Other data items can check if nodes are located on this geometry. The coordinates of the corner points are  $x\_0\ y\_0\ z\_0$  etc.. In 2D, only  $x\_0, y\_0$  etc. should be specified etc.. The points of the quadrilateral should be specified in the correct order; the order is clarified in the example below.

In 2D all **node** inside the quadrilateral (the tolerance is neglected). In 3D all **node** within a distance *tolerance* are considered to be part of the quadrilateral ( this is a brick with thickness *tolerance*). All **node** within a distance *tolerance* are considered to be part of the quadrilateral (in 2D this gives a quadrilateral with corners nodes specified by the corners points, in 3D this gives a brick corners nodes specified by the corners points and with thickness *tolerance*). Internally in TOCHNOG, the quadrilateral is divided into two **geometry\_triangles**, which is only approximately true if the quadrilateral is twisted. Example

```

...
number_of_space_dimensions 2
...
geometry_quadrilateral 0 0. 0. 1. 0. 0. 1. 1. 1. 1.e-3
...

```

Notice the order in which the points are to be specified.

#### 6.545 **geometry\_quadrilateral\_eps\_iso** *index iso\_tolerance*

With this parameter you can ask Tochnog to accept points just outside the quadrilateral in direction of the quadrilateral plane. Typically try  $1.e-3$  for *iso\_tolerance*.

#### 6.546 **geometry\_set** *index geometry\_entity\_0 geometry\_entity\_index\_0 geometry\_entity\_1 geometry\_entity\_index\_1 ...*

This set combines a number of geometrical entities (e.g. **geometry\_circle**, **geometry\_line**, etc.) into a new entity. You cannot use another geometry set for the geometrical entities (that is, geometry sets cannot be nested).

Other data items can check if nodes are located on this geometry.

#### 6.547 **geometry\_sphere** *index x\_c y\_c z\_c radius tolerance*

This data item defines a sphere in space. Other data items can check if nodes are located on this geometry. The coordinate of the center is  $x_c y_c z_c$ . All **node** within a distance *tolerance* of *radius* are considered to be part of the sphere.

#### 6.548 **geometry\_sphere\_segment** *index x\_c y\_c z\_c radius side\_x side\_y side\_z tolerance*

This data item defines a spherical segment in space. Other data items can check if nodes are located on this geometry. The coordinate of the center is  $x_c y_c z_c$ . If *side\_x* is set to a positive value, say +1., then only x-values larger than  $x_c$  are considered to be part of the geometry. If *side\_x* is set to a negative value, say -1., then only x-values smaller than  $x_c$  are considered to be part of the geometry. If *side\_x* is set to 0, then all x-values are considered to be part of the geometry. Likewise remarks hold for y- and z-values.

All **node** within a distance *tolerance* of *radius* are considered to be part of the spherical segment.

**6.549 geometry\_tetrahedral** *index x\_0 y\_0 z\_0 x\_1 y\_1 z\_1 x\_2 y\_2 z\_2 x\_3 y\_3 z\_3*

This data item defines a tetrahedral in space. Other data items can check if nodes are located on this geometry. The coordinates of the corner points are *x\_0 y\_0 z\_0* etc..

**6.550 geometry\_triangle** *index x\_0 y\_0 z\_0 x\_1 y\_1 z\_1 x\_2 y\_2 z\_2 tolerance*

This data item defines a triangle in space. Other data items can check if nodes are located on this geometry. The coordinates of the corner points are *x\_0 y\_0 z\_0* etc.. In 2D the *z* coordinates should not be specified. All **node** within a distance *tolerance* are considered to be part of the triangle (this gives a wedge with thickness *2tolerance*).

**6.551 geometry\_triangle\_eps\_iso** *index iso\_tolerance*

With this parameter you can ask Tochnog to accept points just outside the triangle in direction of the triangle plane. Typically try *1.e - 3* for *iso\_tolerance*.

**6.552 global\_node\_dof\_empty** *switch*

If *switch* is set to **-yes**, the dof's in a node are set to zero when the node is only connected to empty elements. If *switch* is set to **-no**, the dof's in a node are not set to zero when the node is only connected to empty elements. Default *switch* is set to **-yes**.

**6.553 global\_element\_dof\_apply** *switch*

If you set **switch** to **-yes**, then dof's like strains, stresses, etc. will be saved in the element integration points in the records **element\_intpnt\_dof**. So, not the dof's from the global nodes will be used, but each element uses its own values for these dof's in the integration points. This will only be done for dof's like strains, stresses, history variables, etc. Other principal dof's like velocities, temperature, etc. are used from the global nodes.

If you set **switch** to **-no**, then elements will actually use the averaged nodal results, and will not remember its own values.

Default, if **global\_element\_dof\_apply** is not specified, **global\_element\_dof\_apply** is set to **-yes**. See also **global\_element\_dof\_from\_node\_dof**.

Realise that even when the dofs like strains, stresses etc are remembered and stored in integration points, they still be added to the global node dofs to facilitate, for example, plot programs using thse nodal results for plotting. As a special option you can suppressing

this adding to the global nodal dofs by using **-only** for the *switch*; then again the dofs like strains, stresses etc. are remembered in integration points, but now also these dofs are not added to the global node dofs.

#### 6.554 **global\_element\_dof\_from\_node\_dof** *switch*

If **global\_element\_dof\_apply** is set to **-yes**, and the **element\_intpnt\_dof** record does not exist, but **node\_dof** records exist in the input file, you can either require that the **element\_intpnt\_dof** records will be initialised from the **node\_dof** records, or will not be initialised from the **node\_dof** records. If you set *switch* to **-yes** the **element\_intpnt\_dof** records will be initialised from the **node\_dof** records. If you set *switch* to **-no** the **element\_intpnt\_dof** records will not be initialised from the **node\_dof** records. Default, if **global\_element\_dof\_from\_node\_dof** is not specified, *switch* is set to **-no**.

#### 6.555 **global\_post\_point\_node\_type** *node\_type*

With this record you can determine how records like **post\_point**, **control\_print\_dof\_point** and **control\_print\_dof\_line** are evaluated. If *node\_type* is set to **-node** the current nodal coordinates for elements are used to determine for which material point inside elements the dof's should be determined; if you do an updated lagrange calculation in which the coordinates of nodes change, so the **node** records change, you get dof results for the material at the current moment presented on the point or line. If *node\_type* is set to **-node\_start\_refined** the initial start nodal coordinates for elements are used to determine for which material point inside elements the dof's should be determined; thus you get dof results for the material at the initial start moment presented on the point or line.

Default, if this record is not set, *node\_type* is set to **-node\_start\_refined**.

#### 6.556 **groundflow\_apply** *switch*

If *switch* is set to **-no**, then the groundflow equation is skipped, and all groundflow data is ignored. This is done for all timesteps.

#### 6.557 **groundflow\_consolidation\_apply** *switch*

If *switch* is set to **-no**, then the material divergence part in the groundflow equation is skipped. This is done for all timesteps.

Default *switch* is **-no**.

### 6.558 **groundflow\_density** $\rho$

Density of ground water.

### 6.559 **groundflow\_flux\_edge\_normal** *index flux*

Distributed prescribed water flux normal to the edge of an element. This distributed flux is translated into equivalent nodal flux on the edges of elements. Also the record **groundflow\_flux\_edge\_normal\_geometry** should be specified, and optionally the record **groundflow\_flux\_edge\_normal\_time** can be specified.

Attention: this option is only available for linear and quadratic isoparametric elements.

Attention: if this option is used INSIDE a FE mesh, then the elements on each side will get the distributed flux. So the total water flux will normally become zero since the normals of the elements at the side of the geometry are opposite.

### 6.560 **groundflow\_flux\_edge\_normal\_element** *index element\_0 element\_1 ...*

Restricts the elements to which the **groundflow\_flux\_edge\_normal** record with the same *index* should be applied.

### 6.561 **groundflow\_flux\_edge\_normal\_element\_group** *index element\_group\_0 element\_group\_1 ...*

Restricts the element groups to which the **groundflow\_flux\_edge\_normal** record with the same *index* should be applied.

### 6.562 **groundflow\_flux\_edge\_normal\_element\_node** *index element\_node\_0 element\_node\_1 ...*

Selects the element and local node numbers for which the **groundflow\_flux\_edge\_normal** record with the same *index* should be applied.

### 6.563 **groundflow\_flux\_edge\_normal\_element\_node\_factor** *index factor\_0 factor\_1 ...*

Nodal multiplication factors with which the **groundflow\_flux\_edge\_normal** will be applied to the element of **groundflow\_flux\_edge\_normal\_element\_node**. You need

to specify a factor for each node on the side. Here  $factor_0$  is the multiplication factor for the first node on the side, etc.

**6.564** **groundflow\_flux\_edge\_normal\_element\_side** *index element\_0  
element\_1 ... side*

Selects the elements and local side number for which the **groundflow\_flux\_edge\_normal** record with the same *index* should be applied.

**6.565** **groundflow\_flux\_edge\_normal\_factor** *index a\_0 a\_1 ... a\_n*

This data item defines a polynomial in space. This polynomial gives a factor which is used as a multiplication factor for **groundflow\_flux\_edge\_normal** records (with the same index). In this way, you can obtain coordinate dependent water fluxes.

In 1D the polynomial is  $a_0 + a_1x$  (specify 2 values). In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values). In 3D the polynomial is  $a_0 + a_1x + a_2y + a_3z$  (specify 4 values).

**6.566** **groundflow\_flux\_edge\_normal\_geometry** *index geometry\_entity\_name  
geometry\_entity\_index*

Selects the area for which the **groundflow\_flux\_edge\_normal** record with the same *index* should be applied. For example, **-geometry\_line 1** can be used in 2D, indicating that the nodes on line 1 get the distributed flux. The total edge of an element must be inside the geometry for the force to become active. For 2D elements the border lines are edges. For 3D elements the border surfaces are edges.

**6.567** **groundflow\_flux\_edge\_normal\_node** *index node\_0 node\_1 node\_2  
...*

Selects the nodes for which the **groundflow\_flux\_edge\_normal** record with the same *index* should be applied. The *node\_0* etc. specify global node numbers.

**6.568** **groundflow\_flux\_edge\_normal\_sine** *index start\_time end\_time  
freq\_0 amp\_0 freq\_1 amp\_1 ...*

Similar to **force\_edge\_sine**, now for water flux however.

**6.569** `groundflow_flux_edge_normal_time` *index time load time load*  
...

This record specifies a diagram which contains the factors with which the `groundflow_flux_edge_normal` record with the same index is applied. Linear interpolation is used to extend the *time load* values to the intervals between these pairs. Outside the specified time range a factor 0 is used.

If this record is not specified, the flux is applied at all times with a factor 1.

**6.570** `groundflow_nonsaturated_apply` *index switch*

If *switch* is set to **-no**, then nonsaturated groundflow data (eg van Genuchten) will not be applied; only saturated data will be used. This is done for all timesteps.

Default *switch* is **-yes**.

**6.571** `groundflow_phreatic_bounda` *switch*

If *method* is set to **-yes**, the phreatic level is used to automatically prescribe the hydraulic pressure head of nodes which are located on or above the phreatic level.

Default, if `groundflow_phreatic_bounda` is not specified, *method* is set to **-yes**,

**6.572** `groundflow_phreatic_level` ...

Groundwater level.

In a 1D calculation this record should be given *x* value of the groundwater level. The groundwater is below that *x*-value.

In a 2D calculation this record should be given sets of *x* – *y* which specify the *y* level of the groundwater at several *x* locations; In 2D you need to give the *x* – *y* sets as follows:

- specify *x* – *y* sets for increasing *x*

In 3D the phreatic line is specified as follows. Denote the lowest *x* with *x*\_0, the next higher *x* with *x*\_1 etc. Denote the lowest *y* with *y*\_0, the next higher *y* with *y*\_1 etc. Denote the phreatic level *z* value for *x*\_i *y*\_j with *z*\_ij. Then give the following:

- *x*\_0 *y*\_0 *z*\_00 *x*\_1 *y*\_0 *z*\_10 etc.
- *x*\_0 *y*\_1 *z*\_01 *x*\_1 *y*\_1 *z*\_11 etc.

- etc.

In 3d, the number of points in x and y direction respectively should be set with *nx* and *ny* of the **groundflow\_phreatic\_level\_n** record.

In nodes above the phreatic level the total pressure will be set to zero during the calculation.

As a special option in 2D and 3D, you can specify one value only, which sets a constant phreatic level of that value everywhere. In this special case, you do not need to specify **groundflow\_phreatic\_level\_n**.

### 6.573 groundflow\_phreatic\_level\_n nx ny

See **groundflow\_phreatic\_level**.

### 6.574 groundflow\_phreatic\_level\_static switch

If *switch* is set to **-yes**, total pressures (pore pressures) in nodes for which the **groundflow\_phreatic\_level** holds, will be set equal to the static pressure.

This is convenient if the phreatic line is located above the mesh part to which it belongs; then nodes of the mesh will not get a boundary condition, so that the correct hydraulic pressure head can not be determined. And thus, it is necessary to determine the total pressure (pore pressure) from the difference of nodal coordinates and phreatic line height.

It is also convenient if you do not want to initialise and solve the hydraulic pressure heads with the groundflow storage equation. This saves computer memory and CPU time.

In the **group\_type** for elements which should get the static groundflow pressure you need to add **-groundflow**.

### 6.575 groundflow\_phreatic\_level\_multiple index ...

The same as **groundflow\_phreatic\_level**, but now however several groundwater levels can be specified. For each **groundflow\_phreatic\_level\_multiple** you should specify a separate value for *index*.

This option typically can be used if you have in vertical direction non-permeable layers separating the total domain in independent parts with each its own groundwater level.

You can specify with one of **groundflow\_phreatic\_level\_multiple\_element** or **groundflow\_phreatic\_level\_multiple\_element\_geometry** or **groundflow\_phreatic\_level\_multiple\_element\_node** the parts of the domain that belong

to the groundwater level of **groundflow\_phreatic\_level\_multiple** with the same index. Only one of these record can be used, you cannot combine them.

With **groundflow\_phreatic\_level\_multiple\_n** you specify *nx ny* in 3D again.

In the **group\_type** for elements which should get the static groundflow pressure you need to add **-groundflow**.

**6.576** **groundflow\_phreatic\_level\_multiple\_element** *index* **element\_0**  
**element\_1** ...

Element numbers for **groundflow\_phreatic\_level\_multiple** with the same index.

**6.577** **groundflow\_phreatic\_level\_multiple\_element\_group** *index*  
**element\_group\_0** **element\_group\_1** ...

Element group numbers for **groundflow\_phreatic\_level\_multiple** with the same index.

**6.578** **groundflow\_phreatic\_level\_multiple\_element\_geometry** *index*  
**element\_geometry\_0** **element\_geometry\_1** ...

Element geometry numbers for **groundflow\_phreatic\_level\_multiple** with the same index.

**6.579** **groundflow\_phreatic\_level\_multiple\_n** *nx ny*

See **groundflow\_phreatic\_level\_multiple**.

**6.580** **groundflow\_phreatic\_level\_multiple\_node** *index* **node\_0** **node\_1**  
...

Node numbers for **groundflow\_phreatic\_level\_multiple** with the same index.

**6.581** **groundflow\_phreatic\_level\_multiple\_static** *index* **switch**

If *switch* is set to **-yes**, total pressures (pore pressures) in nodes for which the **groundflow\_phreatic\_level\_multiple** holds, will be set equal to the static pressure.

This is convenient if the phreatic line is located above the mesh part to which it belongs; then nodes of the mesh will not get a boundary condition, so that the correct hydraulic pressure head can not be determined. And thus, it is necessary to determine the total pressure (pore pressure) from the difference of nodal coordinates and phreatic line height.

It is also convenient if you do not want to initialise and solve the hydraulic pressure heads with the groundflow storage equation. This saves computer memory and CPU time.

#### **6.582** `groundflow__phreatic__only` *switch*

If *switch* is set to **-yes** groundflow data is removed for groups which are not part of **groundflow\_\_phreatic\_\_level\_\_multiple\_\_element\_\_group** records. Thus only groundflow data is retained for groups for which a multiple phreatic level is defined.

#### **6.583** `groundflow__phreatic__project` *switch*

If *switch* is set to **-yes**, the hydraulic pressure head which is imposed on nodes above the phreatic level uses the project coordinate on the phreatic level (smallest distance); thus not simply the distance in vertical direction. For some calculations that gives better groundwater velocities.

Default, it **groundflow\_\_phreatic\_\_project** is not specified, *switch* is set to **-no**.

#### **6.584** `groundflow__pressure__factor` *factor*

With this record you can specify a factor which is used to add the pore pressure to the effective stress to get the total stress:  $\text{total stress} = \text{effective stress} + \text{factor} * \text{pore pressure}$ .

If you calculate with the van genuchten law, automatically the factor will be set to  $Se$  of that law.

#### **6.585** `groundflow__seepage__eps` *eps*

The *eps* specifies the tolerance if the groundflow seepage condition should be applied or not. If the inner product of the groundflow water flow direction with the normal outside the material is smaller than *eps*, the seepage status will be set to closed, and the total pressure condition will not be applied (so that the boundary is really closed for water flow). If not specified, *eps* is set to 0.1.

**6.586** `groundflow_seepage_geometry` *index geometry\_item\_name geometry\_item\_index*

This record specifies an edge of the groundflow domain for which the groundwater is only allowed to flow outwards of the domain; flow into the domain is not allowed on that edge. The geometrical entity should be specified such that the normal of the geometry points outwards the material (so outwards the groundflow domain). This option comes handy when the point of groundwater flow exit is not known in advance of the calculation; it will be a result of the calculation instead.

Example:

```
...
groundflow_seepage_geometry 10 -geometry_line 100
...
bounda_dof 20 -geometry_line 100 -total_pressure
bounda_time 20 0.0
```

In this example the total pressure (pore pressure) is set to 0 on the geometry line number 100, to account for free air at that edge. Since at that edge water cannot enter the domain the seepage option is applied to that edge. The result of these combined options is that on nodes with outward flow a total pressure 0 boundary condition is imposed, whereas on other nodes no boundary conditions is imposed (so that the flow is 0 at those nodes). The transition point between these outflow nodes and nodes with zero flow will be found automatically as a result of the calculation.

**6.587** `groundflow_seepage_node` *index node\_0 node\_1 ...*

This record does the same as the `groundflow_seepage_geometry` record, but now however you specify node numbers at which the seepage condition holds. The *node\_0* is the first node number, the *node\_1* is the second node number, etc.

**6.588** `groundflow_total_pressure_limit` *limit*

With this record you can specify the maximum allowed total pressure value. Any higher value resulting from the groundflow equations will be cutoff to this value. Default the *limit* is set to 0.

### 6.589 **group\_axisymmetric** *index switch*

If *switch* is set to **-yes**, the calculation becomes axi-symmetrical for the group *index*. Each specified *x* coordinate becomes a radius and *y* becomes the length (=vertical) direction. The z-direction is the axi-symmetric direction. Specify only non-negative *x* coordinates, i.e. define the computational domain in the right half-plane.

This option is only available for groups with isoparametric 1D elements (bar2, ...), or isoparametric 2D elements (tria3, quad4, ...), or for 2D interface elements (quad4 interface, ...).

### 6.590 **group\_beam\_force\_moment\_plasti** *index force\_x\_plasti\_first\_node force\_y\_plasti\_first\_node force\_z\_plasti\_first\_node moment\_x\_plasti\_first\_node moment\_y\_plasti\_first\_node moment\_z\_plasti\_first\_node force\_x\_plasti\_second\_node force\_y\_plasti\_second\_node force\_z\_plasti\_second\_node moment\_x\_plasti\_second\_node moment\_y\_plasti\_second\_node moment\_z\_plasti\_second\_node*

With this record you can set ideally plastic limits on forces and moments in beam elements. You can specify different values for each of the local x, y and z-directions, so that a different plastic behavior can be specified for beams having different properties in the different directions. You can also different values for each of the two nodes.

### 6.591 **group\_beam\_inertia** *index Iyy Izz J*

Bending and torsion properties for beam elements. Here *Iyy* is the area moment of inertia for bending along the local beam y axis, and *Izz* is the area moment of inertia for bending along the local beam z axis, and *J* is the polar moment of inertia for torsion along the local beam x axis.

See also **beam\_rotation** in the initialisation part.

The *index* specifies the element\_group, see **element\_group**.

### 6.592 **group\_beam\_memory** *index memory\_type*

Memory model for beam; either **-updated\_linear**, **-updated** or **-total\_linear**. The **-updated** model is a geometrically nonlinear model which takes large beam rotations into account. The *index* specifies the element\_group, see **element\_group**.

### 6.593 **group\_beam\_direction\_z** *index dir\_z,x dir\_z,y dir\_z,z*

This record specifies the local beam z direction in global space. If **group\_beam\_direction\_z** is not specified in 2D then *0 0 1* will be used. If **group\_beam\_direction\_z** is not specified in 3D then a arbitrary direction perpendicular to the beam length axes will be used.

The local beam axes will be placed in the **element\_beam\_direction** record after the calculation.

The *index* specifies the element\_group, see **element\_group**.

See also **group\_beam\_direction\_z\_reference\_point** for automatic beam z-axis towards a reference point.

### 6.594 **group\_beam\_direction\_z\_reference\_point** *index point\_x point\_y point\_z*

This data record defines a reference point that allows you to influence the local beam z-direction. The local beam z-direction will be setup as follows:

- The length direction of the beam is determined, that is the local beam x-axis.
- A vector is taken from the beam middle point to the reference point.
- The part of this vector perpendicular to the length direction defines the local beam z-axis.

The above procedure ensures that the beam z-axis is perpendicular to the length direction, and that the z-axis points as much as possible to the reference point. As a typical example, you can use this option to take care that the local beam z-axis points to the middle of a tunnel, which is convenient if a tunnel lining with the local z-axis towards the tunnel middle; to do so specify the middle point of the tunnel axis as reference point *point\_x point\_y point\_z*.

### 6.595 **group\_beam\_young** *index E*

Young's modulus for a beam (for bending moment calculation). The *index* specifies the element\_group, see **element\_group**.

### 6.596 **group\_beam\_shear** *index G*

Shear modulus for a beam (for torsion moment calculation). The *index* specifies the element\_group, see **element\_group**.

**6.597 group\_condif\_absorption** *index a*

Absorption coefficient. The *index* specifies the `element_group`, see **element\_group**.

**6.598 group\_condif\_capacity** *index C*

Heat capacity. The *index* specifies the `element_group`, see **element\_group**.

**6.599 group\_condif\_conductivity** *index k<sub>x</sub> k<sub>y</sub> k<sub>z</sub>*

Heat conductivity in x, y and z direction respectively. As a special option you can also specify one value only, which then will be used in each direction. The *index* specifies the `element_group`, see **element\_group**.

**6.600 group\_condif\_density** *index density*

Density for convection-diffusion equation. The *index* specifies the `element_group`, see **element\_group**.

**6.601 group\_condif\_flow** *index beta<sub>1</sub> beta<sub>2</sub> beta<sub>3</sub>*

Known flow field. In 1D only *beta<sub>1</sub>* should be specified, etc. The *index* specifies the `element_group`, see **element\_group**.

**6.602 group\_contact\_spring\_direction** *index dirN<sub>x</sub> dirN<sub>y</sub> dirN<sub>z</sub>*

Normal direction of a `contact_spring`. The *index* specifies the `element_group`, see **element\_group**.

As an alternative, you can specify **element\_contact\_spring\_direction** which allows for specification of the direction for each element separately.

As yet another alternative you can set *switch* in **group\_contact\_spring\_direction\_automatic** to **-yes**. Then the contact spring will automatically determine the directions.

**6.603 group\_contact\_spring\_direction\_automatic** *index switch*

See **group\_contact\_spring\_direction**.

#### 6.604 **group\_contact\_spring\_plasti\_cohesion** *index c*

The normal contact force  $F_N$  is not allowed to become larger than cohesion  $c$  in tension (positive values of  $F_N$ ). If it would become larger, then the contact is broken, a gap is assumed and the contact force  $F_N$  is put to 0. To have really a positive  $F_N$  for extension of the contact spring, the order of the two nodes as specified in the **element** record for the contact spring should be correct.

Notice that when you use **control\_mesh\_generate\_contact\_spring** to obtain the contact spring elements, you are not sure what the first and what the second node of an element will be, and thus you should not use this **group\_contact\_spring\_cohesion** record. Otherwise, it is not important what you use as first and second node, so that **control\_mesh\_generate\_contact\_spring** can be used safely.

If this **group\_contact\_spring\_plasti\_cohesion** is not specified, infinite cohesion is assumed.

The *index* specifies the element\_group, see **element\_group**.

#### 6.605 **group\_contact\_spring\_plasti\_friction** *index f*

With this record you can specify a fixed friction coefficient for contact springs. If this record is not specified, a very large value for  $f$  will be applied.

The *index* specifies the element\_group, see **element\_group**.

See also **group\_contact\_spring\_stiffness** and **group\_contact\_spring\_friction\_automatic**.

#### 6.606 **group\_contact\_spring\_plasti\_friction\_automatic** *index switch*

If *switch* is set to **-yes**, the friction coefficient for contact springs will be determined from the plasticity law angle of neighboring elements. For a neighboring **group\_materi\_plasti\_mohr\_coul** the friction coefficient  $f$  will be set to  $f = (2./3.)\tan\phi$  with  $\phi$  the friction angle in the mohr-coulomb law of the neighboring elements. For a neighboring **group\_materi\_plasti\_diprisco** the friction coefficient  $f$  will be set to a value depending on the parameter  $\gamma$  of that law.

If no neighbor elements with appropriate material law are found, then  $f$  will be set to 0.2.

The *index* specifies the element\_group, see **element\_group**. See also **group\_contact\_spring\_direction\_automatic**.

**6.607** `group_contact_spring_direction_automatic` *planes index switch\_x  
switch\_y switch\_z*

With this option you can help the `group_contact_spring_friction_automatic` by telling in which planes the automatically determined spring direction is allowed to be. If a switch is set to **-yes**, then the direction may have a component in that plane. If a switch is set to **-no**, then the direction may not have a component in that plane. Default all switches are **-yes**.

The *index* specifies the `element_group`, see `element_group`.

**6.608** `group_contact_spring_memory` *index memory\_type*

Memory model for `contact_spring`; either **-updated\_linear**, **-total\_linear**. The *index* specifies the `element_group`, see `element_group`.

**6.609** `group_contact_spring_stiffness` *index k\_N k\_T*

Stiffnesses for contact springs. The force  $F_N$  in normal direction of the contact spring is determined from  $F_N = k_N u_N$  where  $u_N$  is the normal displacement difference of the two nodes (that is, the displacement of the second node in normal direction minus the displacement of the first node in normal direction). The first tangential force  $F_{T1}$  of the contact spring is determined from  $F_{T1} = k_T u_{T1}$  where  $u_{T1}$  is the tangential displacement difference of the two nodes in the first tangential direction; the same is done for the second tangential force. The total tangential force  $\sqrt{F_{T1}^2 + F_{T2}^2}$  cannot exceed  $f F_N$  with  $f$  friction coefficient; then frictional slip occurs and the total tangential force is set to  $f F_N$ . To model continuing stick between two bodies just put the friction coefficient  $f$  very high.

In 1D the parameters  $k_T$  and  $f$  will not be used (but should be specified as dummies nevertheless).

The *index* specifies the `element_group`, see `element_group`.

See also `group_contact_spring_friction` and `group_contact_spring_friction_automatic`.

**6.610** `group_dof_initial` *index dof\_0 dof\_1 ...*

Same as `element_dof_initial`, now specified for a group of elements however.

#### 6.611 **group\_dof\_initial\_specific\_number** *index dof*

Same as **element\_dof\_initial\_specific\_number**, now specified for a group of elements however.

#### 6.612 **group\_dof\_initial\_specific\_value** *index value\_0 value\_grad\_x value\_grad\_y value\_grad\_z*

Same as **element\_dof\_initial\_specific\_value**, now specified for a group of elements however.

#### 6.613 **group\_groundflow\_capacity** *index C*

Capacity in ground water flow equation. The *index* specifies the **element\_group**, see **element\_group**.

#### 6.614 **group\_groundflow\_consolidation\_apply** *index switch*

If *switch* is set to **-no** consolidation will not be applied for the elements of the group.

#### 6.615 **group\_groundflow\_expansion** *index $\alpha$*

Thermal expansion coefficient for ground water, for a combined groundwater with temperature analysis. The *index* specifies the **element\_group**, see **element\_group**.

#### 6.616 **group\_groundflow\_nonsaturated\_eps\_permeability** *index eps*

The nonsaturated law lowers the permability relative to the specified linear permeability as specified in **group\_groundflow\_permeability**. With this **group\_groundflow\_nonsaturated\_eps\_permeability** you can specify the lowest allowed factor for reducing the permeability.

#### 6.617 **group\_groundflow\_nonsaturated\_vangenuchten** *index $S_{\text{residu}}$ $S_{\text{sat}}$ $g_a$ $g_l$ $g_n$*

Parameters for non-saturated van Genuchten ground water flow, see the theory section. The *index* specifies the **element\_group**, see **element\_group**.

Since the van-Genuchten law is highly nonlinear, convergence of the calculation can be difficult. Always check if the calculation converges by printing **post\_node\_rhside\_ratio**. You can try including inertia to improve convergence.

#### 6.618 **group\_groundflow\_permeability** *index pe<sub>x</sub> pe<sub>y</sub> pe<sub>z</sub>*

Permeability coefficient in ground water flow, in each space direction. In 1D you only should specify *pe<sub>x</sub>*, etc. If you specify only value, then that will be used in each direction. The *index* specifies the **element\_group**, see **element\_group**.

#### 6.619 **group\_groundflow\_permeability\_vertical\_stress** *index a b σ<sub>0</sub> minimum maximum*

This is a special purpose equation for the permeability coefficient in ground water flow:

$$k^p = \frac{a}{(\sigma_v/\sigma_0)^b}$$

where *a* and *b* and  $\sigma_0$  are user specified parameters, and  $\sigma_v$  is the vertical effective stress. The permeability calculated this way is not allowed to become smaller than *minimum* and larger then *maximum*.

This option should only be used in 2D or 3D. This option should be used in combination with **group\_groundflow\_permeability**; the permeability as specified in **group\_groundflow\_permeability** will then be used in regions where the vertical stress is extremely small, to prevent division by zero; in all other regions the permeability as specified by this **group\_groundflow\_permeability\_vertical\_stress** law will be used.

The *index* specifies the **element\_group**, see **element\_group**.

#### 6.620 **group\_groundflow\_total\_pressure\_tension** *index plastic\_tension\_minimum water\_height*

Using this option you can control that the water pressure in an element is at least the value as determined from the specified *water\_height*. More precise, if the static water pore pressure as determined from the water density, the gravity and the *water\_height* exceeds the pore water pressure from the groundflow equation (in absolute terms) , this static water pressure actually is used. This is only done if the largest eigenvalue of **materi\_strain\_plastic\_tension** exceeds *plastic\_tension\_minimum*. To calculate the eigenvalues of **materi\_strain\_plastic\_tension** you need to include **post\_calcul-materi\_strain\_plasti\_tension-prival** in the input file.

This option comes handy to take care that in cracks in concrete actually the largest water pressure from an environment is used. It so ensures that a critical safety analysis for concrete cracking is obtained.

### 6.621 `group_integration_method` *index method*

Here *method* sets the integration method for bars, quad en hex elements. You can either set *method* to **-gauss**, **-lobatto** or **-reduced**.

The gauss and lobatto integration method are explained in text books on finite element methods. The reduced method is a weighted combination of lobatto and 1-point cell centered integration. The weighting is set by the `group_integration_method_reduced_factor` record.

If this record is not set, the default method as described in `group_integration_points` is chosen.

It is advised to keep the default method, so not specify this `group_integration_method` record, unless you know what you are doing.

### 6.622 `group_integration_method_reduced_factor` *index factor*

When *factor*=1 the reduced method is in fact lobatto integration. When *factor*=infinite the reduced method is in fact 1-point cell centered integration. When the *factor* is in between 1 and infinity the intergation is done with a weighted combination of the lobatto and 1-point cell centered integration.

Default the *factor* is set to 10.

### 6.623 `group_integration_points` *index type*

Here *type* sets the number of integration points in an element. It should be set to **-normal**, **-minimal** or to **-maximal**.

For **-tria3** elements the integration point will be located in the middle with **-minimal** integration, or a four-point integration scheme will be used with **-maximal** integration.

For **-tria6** elements a seven-point scheme will be used for **-maximal** and a four-point scheme will be used with **-minimal** integration.

For **-tet4** elements the integration point will be located in the middle with **-minimal** integration, or a five-point integration scheme will be used with **-maximal** integration.

For **-tet10** elements a five-point scheme will be used for **-minimal** and a ten-point scheme will be used with **-maximal** integration.

For other elements, if **-minimal** is used then the number of integration points in a direction is set equal to the number of nodes in the direction minus 1, and gauss integration is used. If for the other elements **-maximal** is used then the number of integration points in a direction is set equal to the number of nodes in the direction; gauss integration is used, but in case

inertia is applied then lobatto integration will be used.

Default **-minimal** is used for **-bar2**, **-tria3**, and **-tet4** elements; it is default **-maximal** otherwise.

If *type* is set to **-normal**, the default integration will be used.

The above is valid for normal isoparametric elements. For interface elements default lobatto integration is used (integration points in nodes).

It is advised to keep the default method, so not specify this **group\_integration\_points** record.

The *index* specifies the element\_group, see **element\_group**.

#### 6.624 **group\_interface\_index** *switch*

With this record, you set that the element with element group *index* will act as an interface element by setting *switch* to **-yes**. This is available for **-quad4**, **-quad6**, **-hex8**, **-hex18**, **-prism6** and **-prism12**.

See **group\_interface\_\*** which data can be set for interfaces.

In interfaces strains are displacement differences between the opposite interface sides.

#### 6.625 **group\_interface\_condif\_conductivity** *index k*

The 'index' specifies the group number. The conductivity *k* specifies the heat flow in interface thickness direction per unit temperature difference. Thus the conductivity is not the material conductivity but the conductivity of the layer simulated by the interface incorporating the thermal thickness of the interface, The 'conductivity' has units [power]/[temperature\*length] in 2D, and [power]/[temperature\*length\*length] in 3D.

#### 6.626 **group\_interface\_gap** *index gap*

By specifying this record you can account for initial empty space between the sides of an interface element. Only when the sides displacements are such that the normal strain becomes lower then the specified *gap* value the interface will be closed and start to generate stresses.

So typically you set *gap* to a negative number if there is a physical gap.

If you want to allow always tension stresses in an interface set *gap* to, by example, 1.e20.

### 6.627 `group_interface_groundflow_capacity` *index C*

This record specifies the capacity for interface elements.

### 6.628 `group_interface_groundflow_permeability` *index pe*

This record specifies the permeability per unit length in 2D or unit area in 3D for interface elements.

### 6.629 `group_interface_materi_elasti_stiffness` *index kn kt,first kt,second*

This record allows you to specify a normal stiffness and tangential shear stiffnesses for discrete interface elements with **-materi** in **group\_type**. Normal stresses in the interface element follow from normal strains multiplied with *kn* ( $\text{stress,normal} = \text{kn} * \text{strain,normal}$ ). Shear stresses in the interface element in the first tangential direction follow from shear strains in the first tangential direction multiplied with *kt,first* ( $\text{stress,shear,first} = \text{kt,first} * \text{shear,gamma,first} = 2 * \text{kt,first} * \text{strain,shear,first}$ ). Shear stresses in the interface element in the second tangential direction follow from shear strains in the second tangential direction multiplied with *kt,second* ( $\text{stress,shear,second} = \text{kt,second} * \text{shear,gamma,second} = 2 * \text{kt,second} * \text{strain,shear,second}$ ). The *kt,second* should be specified for 3D interfaces only.

Too high values for interface stiffness will cause convergence problems in calculations. Thus, if you are running a calculation with interface elements and you are experiencing convergence problems please try lower values for the interface stiffnesses. Typically the normal interface stiffness can be chosen as 10 times the Young's modulus of the neighbouring isoparametric element divided by the length of that element in normal direction. Typically the tangential interface stiffness can be chosen as half of the normal interface stiffness.

Attention: an interface will only build up stresses if the interface normal strain is not larger than the gap specified in **group\_interface\_gap**. If the interface normal strain is larger than the gap, then the interface status is considered to be opened, and the interface does not have stresses.

A 3d example:

```
...
number_of_space_dimensions 3
...
group_interface_materi_elasti_stiffness 0 0.10000e+11 0.50000e+10
0.50000e+10
...
```

### 6.630 **group\_interface\_materi\_expansion\_normal** *index expansion\_coefficient\_normal*

The 'index' specifies the group number. The *expansion\_coefficient\_normal* specifies the thermal strain expansion in interface thickness direction per unit temperature in the interface. The temperature is the average of the temperature of the both sides at the location of the integration point. This option is only available if **group\_interface\_materi\_memory** is set to **-total\_linear** or **-updated\_linear**. Furthermore, **materi\_strain\_elasti** should be initialised.

### 6.631 **group\_interface\_materi\_memory** *index memory\_type*

Either *memory\_type* should be set to **-updated\_linear** or **-total\_linear**.

### 6.632 **group\_interface\_materi\_plasti\_mohr\_coul\_direct** *index phi c phiflow*

Mohr-coulomb plasticity model for interfaces. The angles are in radians. The cohesion  $c$  has stress unit (so just the same as for **group\_materi\_plasti\_mohr\_coul** in normal isoparametric elements). The maximum friction force in the interface is  $c + F_n * \tan(\phi)$  where  $c$  is the cohesion,  $\phi$  is the friction angle in radians and  $F_n$  is the normal force (which is a negative value under compression).

### 6.633 **group\_interface\_materi\_plasti\_tension\_direct** *index tension\_limit*

With this record you can specify the tension limit in interface elements. You may want to set **group\_interface\_gap** to a large value if you want a tensile stress for opening interfaces.

### 6.634 **group\_interface\_materi\_residual\_stiffness** *index factor*

With *factor* you can set the part of the original stiffness to be used as stiffness in opened interfaces. Default, if this record is not specified, the *factor* is set to some small value.

### 6.635 **group\_interface\_groundflow\_total\_pressure\_tension** *index strain\_normal\_minimum\_water\_height*

Using this option you can control that the water pressure in an interface element is at least the value as determined from the specified *water\_height*. More precise, if the static water pore pressure as determined from the water density, the gravity and the *water\_height* exceeds the pore water pressure from the groundflow equation (in absolute terms) , this

static water pressure actually is used. This is only done if the interface normal strain (displacement difference between interface sides) exceeds *strain\_normal\_minimum*.

This option comes handy to take care that in cracks in concrete actually the largest water pressure from an environment is used. It so ensures that a critical safety analysis for concrete cracking is obtained.

### 6.636 **group\_interface\_tangential\_reference\_point** *index point\_x point\_y point\_z*

This data record defines a reference point that allows you to influence the tangential directions in a 3D interface element. The tangential directions will be setup as follows:

- The normal direction to the interface plane is determined.
- A vector is taken from the integration point in the interface element to the reference point.
- The part of this vector perpendicular to the normal direction defines the first tangential direction.
- The outer product of the normal direction and the first tangential direction gives the second tangential direction.

The above procedure ensures that the tangential directions are perpendicular to the normal direction, and that the first tangential directions points as much as possible to the reference point. As a typical example, you can use this option to take care that the first tangential direction points to the middle of a tunnel, so the first tangential interface direction equals in fact the tunnel radial direction; to do so specify the middle point on the tunnel axis as reference point *point\_x point\_y point\_z*.

If this **group\_interface\_tangential\_reference\_point** is not specified, it is only certain that the tangential directions are in plane of the interface (perpendicular to the normal direction), but are not defined otherwise.

See also **element\_interface\_intpnt\_direction**.

### 6.637 **group\_materi\_damage\_mazars** *index epsilon<sub>0</sub> a<sub>t</sub> b<sub>t</sub> a<sub>c</sub> b<sub>c</sub> β*

Parameters for the Mazars damage law. The *index* specifies the element\_group, see **element\_group**.

### 6.638 **group\_materi\_damping** *index d*

Material damping coefficient *d*. See also the dynamics section near the end of this manual.

The *index* specifies the element\_group, see **element\_group**.

#### 6.639 **group\_materi\_damping\_method** *index method*

See **group\_materi\_damping**.

#### 6.640 **group\_materi\_density** *index density*

Density for material flow equation. The *index* specifies the element\_group, see **element\_group**.

#### 6.641 **group\_materi\_density\_groundflow** *index density\_wet density\_dry*

Density for material flow equation when a calculation is performed in combination with groundflow. If the element is filled with groundwater the *density\_wet* will be used and otherwise the *density\_dry* will be used. To determine if an element is filled with water, tochnog does not the following: If **post\_calcul-groundflow\_pressure-total\_pressure** is put in the input file then total pressures (pore pressures) are calculated. Then if the pore pressure in an element is negative the wet density is taken. Otherwise the dry density. If **post\_calcul-groundflow\_pressure-total\_pressure** is NOT put in the input file the total pressures are not calculated. Then tochnog looks if a phreatic level is given; if so, then if an element is below the phreatic level the wet density is used, otherwise if an element is above the phreatic level the dry density is used.

Here *density\_wet* is the amount of kg of soil + water in a unit volume. And *density\_dry* is the amount of kg of soil in a unit volume.

The *index* specifies the element\_group, see **element\_group**.

In case total pressures are calculated

In case total pressures are calculated from the **post\_calcul groundflow\_pressure-total\_pressure** command, the *density\_wet* will be used if the total pressure is smaller than 0, whereas *density\_dry* will be used if the total pressure is larger or equal to 0.

In case total pressures are not calculated but a phreatic level is specified

In case an element is above a specified phreatic level the *density\_dry* will be used. In case an element is below a specified phreatic level, the *density\_wet* will be used.

In other cases

In other cases *density\_dry* will be used.

#### 6.642 **group\_materi\_elasti\_borja\_tamagnini** *index* $G_0 \propto \hat{k} p_r$

Elastic data for the modified Borja Tamagnini model, see [1]. The *index* specifies the `element_group`, see **element\_group**.

#### 6.643 **group\_materi\_elasti\_c** *index* 81 values

With this record you can directly specify the 81 values of the linear material stiffness  $C_{ijkl}$  which will be used to calculate stresses from strains with  $\sigma_{ij} = C_{ijkl}\epsilon_{kl}$ . Here  $\sigma_{ij}$  is the stress matrix and  $\epsilon_{kl}$  is the strain matrix.

The sequence of strains and stresses is xx, xy, xz, yx, yy, yz, zx, zy and zz.

The 81 values should be specified row by row, where each row contains 9 values. See also **group\_materi\_elasti\_c\_direction**.

#### 6.644 **group\_materi\_elasti\_c\_direction** *index* *dir\_0* *dir\_1* *dir\_2*

This record specifies local axes for which the **group\_materi\_elasti\_c** is specified. In total 9 values need to be specified, first the 3 values for *dir\_0*, then the 3 values for *dir\_1* and then the 3 values for *dir\_2*. Default, if this record is not specified, the global axes will be used.

#### 6.645 **group\_materi\_elasti\_camclay\_g** *index* $G$

Elastic data  $G$  for the modified CamClay model. The *index* specifies the `element_group`, see **element\_group**.

#### 6.646 **group\_materi\_elasti\_camclay\_poisson** *index* $\nu$

Elastic data  $\nu$  for the modified CamClay model. This option is alternative to the **group\_materi\_elasti\_camclay** option (so, only one of both can be defined). With this option the poisson ratio  $\nu$  is assumed constant, and is used as follows:

$$G = \frac{3}{2}K(1 - 2\nu)/(1 + \nu)$$

The *index* specifies the `element_group`, see **element\_group**.

#### 6.647 **group\_materi\_elasti\_camclay\_pressure\_min** *index pressure\_min*

This specifies a minimal allowed value for the pressure in the calculation of the bulk modulus for the camclay model. In the calculation pressures below *pressure\_min* will be set to *pressure\_min*. This prevents numerical problems for very low bulk modulus  $K$  values.

The *index* specifies the **element\_group**, see **element\_group**.

#### 6.648 **group\_materi\_elasti\_compressibility** *index co*

Compressibility for materials. A positive value should be used. The *index* specifies the **element\_group**, see **element\_group**.

#### 6.649 **group\_materi\_elasti\_hardsoil** *index $E_{50}^{ref}$ $\sigma_{50}^{ref}$ $\nu_{50}$ $m$ $E_{ur}^{ref}$ $\sigma_{ur}^{ref}$ $\nu_{ur}$*

Elasticity data for Hardening Soil model. The *index* specifies the **element\_group**, see **element\_group**.

#### 6.650 **group\_materi\_elasti\_k0** *index K0*

Elastic data  $K0$ . When this data is specified, and also **control\_materi\_elasti\_k0** is set to -yes, then the  $K0$  parameter will be used in the elastic stress law with **group\_materi\_elasti\_young** or **group\_materi\_elasti\_young\_power** and **group\_materi\_elasti\_poisson**, or with **group\_materi\_elasti\_hardsoil**. In fact it will be used to determine the poisson coefficient consistent with the  $K0$ ; this poisson coefficient is used in the elastic stress law.

This **group\_materi\_elasti\_k0** in combination with **control\_materi\_elasti\_k0** is a convenient method to get 'K0 stresses' when imposing gravity in a geotechnics calculation. After gravity is imposed simply do not set the **control\_materi\_elasti\_k0** anymore, so that the normal **group\_materi\_elasti\_poisson** will be used in the remaining steps.

For  $K0 > 0.95$  Tochnog will take 0.95.  $K0$  exceeding 1 (or 0.95) may lead to ill-conditioned calculations.

#### 6.651 **group\_materi\_elasti\_lade** *index B R $\lambda$*

Elastic data  $B = 0$ ,  $R$ ,  $\lambda$  for the Lade model. The *index* specifies the **element\_group**, see **element\_group**.

#### 6.652 **group\_materi\_elasti\_poisson** *index poisson*

Poisson ratio for solid. The *index* specifies the `element_group`, see **element\_group**.

#### 6.653 **group\_materi\_elasti\_poisson\_power** *index $\nu_0 \nu_1 \nu_2 p_{-1} \alpha$*

Power law poisson ratio for solid material. See the theory part. The *index* specifies the `element_group`, see **element\_group**.

#### 6.654 **group\_materi\_elasti\_shear\_factor** *index factor*

Specifying this record causes the shear stiffness following from a specified young and poisson to be multiplied with *factor*. This provides a convenient way to test in a calculation what the effect of low shear stresses is. The *index* specifies the `element_group`, see **element\_group**.

#### 6.655 **group\_materi\_elasti\_stress\_pressure\_history\_factor** *index factor*

This record allows you to model a different soil stiffness when first loading or unloading/reloading instead. The **materi\_stress\_pressure\_history** should be initialised, which records the maximum soil pressure that occurred in history. If the current pressure is smaller then the largest pressure in history, the material is unloading or reloading, and the stiffness will be multiplied with *factor*. If the current pressure is the larger then the largest pressure from history, then this current pressure becomes the maximum history pressure, and the stiffness will not be multiplied with *factor*.

This **group\_materi\_elasti\_stress\_pressure\_history\_factor** can be combined with the young as specified by **group\_materi\_elasti\_young** or the young calculated from **group\_materi\_elasti\_young\_power**.

Typically the factor has a value of about 3.

#### 6.656 **group\_materi\_elasti\_transverse\_isotropy** *index $E_1 E_2 \nu_1 \nu_2 G_2 \text{dir}_x \text{dir}_y \text{dir}_z$*

Specifies the unique direction (*dir\_x dir\_y dir\_z*) and elastic moduli in the transverse isotropic model. Here  $E_2$  is the young modulus in the unique direction,  $E_1$  is the young modulus in both directions perpendicular to the unique direction, etc. The *index* specifies the `element_group`, see **element\_group**.

### 6.657 **group\_materi\_elasti\_volumetric\_poisson** *index* $\nu$

See **group\_materi\_elasti\_volumetric\_young\_values**

### 6.658 **group\_materi\_elasti\_volumetric\_young\_order** *index* $n$

See **group\_materi\_elasti\_volumetric\_young\_values**

### 6.659 **group\_materi\_elasti\_volumetric\_young\_values** *index* $\epsilon_0 \sigma_0 \epsilon_1 \sigma_1 \dots$

This is a special record to model the volumetric stress part of a nonlinear material, given the experimental results of a volumetric compression test (compression in one direction, fixed size in other two directions).

The table  $\epsilon_0 \sigma_0 \epsilon_1 \sigma_1 \dots$  specifies the strain-stress results for the volumetric compression test. Together with the poisson ratio as specified in **group\_materi\_elasti\_volumetric\_poisson** an isotropic law in a nonlinear Young's modulus and a constant poisson ratio is fitted to this experiment. The Young modulus in fact is taken as the polynomial expansion  $E_0 + E_1\epsilon + E_2\epsilon^2 + \dots + E_{n-1}\epsilon^{n-1}$  where  $n$  denotes the order of the polynomial expansion (as given in **group\_materi\_elasti\_volumetric\_young\_order**).

The poisson ratio should be taken very high, say 0.4999999 or so, to ensure that the resulting law only models volumetric stresses. Then afterwards a normal young-poisson isotropic law (**group\_materi\_elasti\_young** and **group\_materi\_elasti\_poisson**) can be added to get an extra deviatoric part.

### 6.660 **group\_materi\_elasti\_young** *index* $E$

Young's modulus for solid material. The *index* specifies the element\_group, see **element\_group**.

### 6.661 **group\_materi\_elasti\_young\_polynomial** *index* $E_0 E_1 \dots$

Polynomial parameters for strain dependent Young's modulus for solid material. See the theory part. The *index* specifies the element\_group, see **element\_group**.

### 6.662 **group\_materi\_elasti\_young\_power** *index* $E_0 E_1 E_2 E_3 p_{-1} \alpha$

Power law Young's modulus for solid material. See the theory part. The *index* specifies the element\_group, see **element\_group**.

If you want to get the calculated young as output, initialise with **materi\_history\_variable 1**; the history variable will be filled with the calculated young, and can be plotted for example in GID.

#### 6.663 **group\_materi\_elasti\_young\_user** *index switch*

If *switch* is set to **-yes** the user supplied routine **user\_young** will be called. There the youngs modulus should be calculated from the solution fields and the stress history. Typically degradation of material stiffness for cyclic loading can be programmed with this user specified routine.

You can plot in gid the values for the young as follows:

```
...  
print_group_data -group_materi_elasti_young  
...
```

#### 6.664 **group\_materi\_expansion\_linear** *index $\alpha$*

Linear expansion coefficient. The *index* specifies the `element_group`, see **element\_group**.

#### 6.665 **group\_materi\_expansion\_volume** *index $\beta$*

Volume expansion coefficient. The *index* specifies the `element_group`, see **element\_group**.

#### 6.666 **group\_materi\_factor** *index factor*

This factor comes convenient if your material stress law is specified in other units then you actually want in your calculation. Then you can specify *factor* to take care that your material stresses become consistent with the remaining part of the input file. For example, if you want your input file to work with kPa but your material stress law works with MPa then simply set *factor* to 1000.

#### 6.667 **group\_materi\_failure\_crunching** *index threshold delete\_time*

If the compression strain in an element exceeds *threshold*, the element is considered to be fail. The element will be slowly deleted. It is totally deleted if the *delete\_time* has passed.

The *index* specifies the `element_group`, see **element\_group**.

#### **6.668** `group_materi_failure_damage` *index threshold delete\_time*

If the damage in an element exceeds *threshold*, the element is considered to be fail. The element will be slowly deleted. It is totally deleted if the *delete\_time* has passed.

The *index* specifies the element\_group, see **element\_group**.

#### **6.669** `group_materi_failure_plasti_kappa` *index threshold delete\_time*

If the plastic parameter kappa in an element exceeds *threshold*, the element is considered to be fail. The element will be slowly deleted. It is totally deleted if the *delete\_time* has passed.

The *index* specifies the element\_group, see **element\_group**.

#### **6.670** `group_materi_failure_rupture` *index threshold delete\_time*

If the tensile strain in an element exceeds *threshold*, the element is considered to be fail. The element will be slowly deleted. It is totally deleted if the *delete\_time* has passed.

The *index* specifies the element\_group, see **element\_group**.

#### **6.671** `group_materi_failure_void_fraction` *index threshold delete\_time*

If the void fraction in an element exceeds *threshold*, the element is considered to be fail. The element will be slowly deleted. It is totally deleted if the *delete\_time* has passed.

The *index* specifies the element\_group, see **element\_group**.

#### **6.672** `group_materi_history_variable_user` *index switch*

Set *switch* to **-yes** if you want to activate the user supplied routine for material history variables. The *index* specifies the element\_group, see **element\_group**.

#### **6.673** `group_materi_history_variable_user_parameters` *index ...*

Specify parameters for the user supplied routine for material history variables. The *index* specifies the element\_group, see **element\_group**.

**6.674** `group_materi_hyper_besseling` *index*  $K_1 K_2 \alpha$

Parameters for Besseling Hyper elastic rubber model. The *index* specifies the `element_group`, see `element_group`.

**6.675** `group_materi_hyper_blatz_ko` *index*  $G\beta$

Parameters for Blatz-Ko model. The *index* specifies the `element_group`, see `element_group`.

**6.676** `group_materi_hyper_mooney_rivlin` *index*  $K_1 K_2$

Parameters for Mooney-rivlin hyper elastic rubber model. The *index* specifies the `element_group`, see `element_group`.

**6.677** `group_materi_hyper_neohookean` *index*  $K_1$

Parameter for Neo-Hookean hyper elastic rubber model. The *index* specifies the `element_group`, see `element_group`.

**6.678** `group_materi_hyper_reduced_polynomial` *index*  $K_1 K_2 \dots$

Parameters for reduced polynomial hyper elastic rubber model. The *index* specifies the `element_group`, see `element_group`.

**6.679** `group_materi_hyper_volumetric_linear` *index*  $K$

Parameter for the linear volumetric hyperelasticity model. The *index* specifies the `element_group`, see `element_group`.

**6.680** `group_materi_hyper_volumetric_murnaghan` *index*  $K\beta$

Parameter for the murnaghan volumetric hyperelasticity model. The *index* specifies the `element_group`, see `element_group`.

### 6.681 `group_materi_hyper_volumetric_ogden` *index* $K\beta$

Parameter for the ogden volumetric hyperelasticity model. The *index* specifies the element\_group, see `element_group`.

### 6.682 `group_materi_hyper_volumetric_polynomial` *index* $K_0 K_1 \dots$

Parameters for the polynomial volumetric hyperelasticity model. The *index* specifies the element\_group, see `element_group`.

### 6.683 `group_materi_hyper_volumetric_simo_taylor` *index* $K$

Parameter for the simo-taylor volumetric hyperelasticity model. The *index* specifies the element\_group, see `element_group`.

### 6.684 `group_materi_maxwell_chain` *index* $E_0 t_0 \dots E_{n-1} t_{n-1}$

In total  $n$  parallel maxwell chains are defined with stiffness  $E_0$ , relaxation time  $t_0$ , etc..

The number  $n$  should equal `materi_maxwell_stress` in the input initialization part. The *index* specifies the element\_group, see `element_group`.

### 6.685 `group_materi_membrane` *index* *switch*

If `switch` is set to `-yes` the  $zz$  stress becomes zero in 2D and the  $yy$  and  $zz$  stress become zero in 1D (in combination with axi-symmetry in 1D, only the  $yy$  stress becomes zero since  $zz$  is the axi-symmetric direction). So this option models plane stress conditions.

If `group_materi_membrane` is not used the plane strain conditions are used. Always the  $z$ -thickness is 1. in 3D, and the  $y$ , and  $z$ -thickness are 1. in 2D; see however also `volume_factor`.

The `group_materi_membrane` option cannot be used in combination with `group_materi_elasti_compress`, `group_materi_hyperelasticity` and `group_materi_viscosity`.

The *index* specifies the element\_group, see **element\_group**.

### 6.686 **group\_materi\_memory** *index memory\_type*

Either *memory\_type* should be set to **-updated**, **-updated\_jaumann**, **-updated\_linear**, **-total** or **-total\_linear**. See the theoretical part for some explanation.

For an linear total Lagrange solid the input file may look like, and is recommended for most solid calculations:

```
...
materi_velocity
materi_displacement
materi_strain_total
materi_stress
end_initia
...
node 1 ...
node 2 ...
...
group_materi_memory 0 -total_linear
group_materi_elasti_young 0 ...
...
end_data
```

For a large deformation total Lagrange solid with a straightforward decomposition of the deformation tensor into a rotation tensor and a stretch tensor the input file may look like

```
...
materi_velocity
materi_displacement
materi_strain_total
materi_stress
end_initia
...
group_materi_memory 0 -total
group_materi_elasti_young 0 ...
...
end_data
```

For an updated Lagrange solid the input file may look like

```
...
```

```

materi_velocity
materi_velocity_integrated
materi_stress
end_initia
...
mesh -follow_material ...
...
node 1 ...
node 2 ...
...
group_materi_memory 0 -updated
group_materi_elasti_young 0 ...
...
end_data

```

Notice that for an updated Lagrange formulation you should always set that the mesh follows the material.

For a fluid the input file may look like

```

...
materi_velocity
materi_stress
end_initia
...
(use Eulerian mesh)
mesh -fixed_in_space ...
timestep_predict_velocity -yes
...
node 1 ...
node 2 ...
...
group_materi_memory 0 -updated_linear
group_materi_viscosity 0 ...
group_materi_elasti_compressibility 0 ...
...
end_data

```

The *index* specifies the element\_group, see **element\_group**.

## 6.687 group\_materi\_plasti\_bounda *index index\_0 index\_1 ...*

With this option, you can model reduction of friction of soil material and alike granular materials on walls. Set *index\_0*, *index\_1* etc. to the index of the **bounda\_dof** records

for which you want to use this reduction. We define an element to be on a wall when at least one of the velocities (displacements) of the elements is prescribed (via **bounda\_dof**). As a special option, you can use **-all** which indicates that the **bounda\_dof** records for all indeces will be used.

The reduction of friction is done for  
**group\_materi\_plasti\_mohr\_coul**,  
**group\_materi\_plasti\_mohr\_coul\_direct**,  
**group\_materi\_plasti\_druck\_prag**,  
**group\_materi\_plasti\_hardsoil**, if specified,  
 by reducing the friction angle  $\phi$  and dilatancy angle  $\phi_{flow}$   
 and cohesion  $c$  of the granular material with a factor (2./3.).

This is done for **group\_materi\_plasti\_camclay**, if specified, by reducing  $M$  with a factor (2./3.).

This is done for **group\_materi\_plasti\_hypo\_\***, if specified, by reducing deviatoric stress increments with a factor (2./3.).

The *index* specifies the element\_group of the granular material, see **element\_group**.

See also **group\_materi\_plasti\_bounda\_factor** and **group\_materi\_plasti\_mohr\_coul\_direct\_wall**.

#### 6.688 **group\_materi\_plasti\_bounda\_factor** *index factor*

With this record you can specify a factor other then the default 2./3. used by the **group\_materi\_plasti\_bounda\_factor** record. You need to specify a factor for each of *index\_0*, *index\_1* etc. If you specify one factor only it will be used for all boundaries.

The *index* specifies the element\_group of the granular material, see **element\_group**.

#### 6.689 **group\_materi\_plasti\_coord\_limit** *index coord\_limit*

To prevent plasticity problems near free surfaces, you can require that Tochnog neglects plasticity laws if the vertical coordinate exceeds *coord\_limit*. This option is not available for hypoplasticity laws, since for these laws nonlinear elasticity and plasticity are defined by one law, so the plasticity part cannot be suppressed by itself.

#### 6.690 **group\_materi\_plasti\_camclay** *index M $\kappa$ $\lambda$*

Plastic data  $M$ ,  $\kappa$  and  $\lambda$  for the modified CamClay model. The *index* specifies the element\_group, see **element\_group**.

**6.691** `group_materi_plasti_cap1` *index*  $\phi$   $c$   $M$   $\lambda^*$   $\kappa^*$   $K^{ref}$   $p^{ref}m$

Plastic data for the cap1 plasticity model.

The *index* specifies the `element_group`, see `element_group`.

**6.692** `group_materi_plasti_cap2` *index*  $c$   $\phi$   $\alpha$   $R$   $\epsilon_v^p$   $p_b \dots$

Plastic data for the cap2 plasticity model. The  $\epsilon_v^p$   $p_b \dots$  represents a table with  $\epsilon_v^p$  versus  $p_b$  values; at least two sets of values need to be specified.

The *index* specifies the `element_group`, see `element_group`.

**6.693** `group_materi_plasti_compression` *index*  $sigy$

Yield data for compression plasticity. The *index* specifies the `element_group`, see `element_group`. Condition: `materi_strain_plasti` should be initialized.

**6.694** `group_materi_plasti_compression_direct` *index*  $sigy$

Compression limit. Principal stresses lower than  $sigy$  are not allowed and will be cut off by Tochnog. This model uses directly a cut-off of stresses, and does not use plastic strains. The *index* specifies the `element_group`, see `element_group`.

You can apply softening with a `dependency_diagram` on `materi_strain_total_compression_kappa`.

**6.695** `group_materi_plasti_compression_direct_visco` *index*  $tm$

Characteristic relaxation time for visco plasticity with `group_materi_plasti_compression_direct`. Choose  $tm$  small if you want to have fast relaxation of the plasticity to the plastic state.

Thus the `group_materi_plasti_compression_direct` can only use this `group_materi_plasti_compression_direct_visco` for visco-plasticity, and no other visco-plasticity model.

See also `group_materi_plasti_mohr_coul_direct_visco`.

**6.696** `group_materi_plasti_diprisco` *index*  $\gamma$   $\hat{\beta}_f$   $b_p$   $c_p$   $t_p$   $\hat{\theta}_c$   $\hat{\theta}_e$   $\xi_c$   $\xi_e$   $\beta_f^0$

Yield data for di Prisco plasticity. The *index* specifies the `element_group`, see `element_group`. Condition: `materi_strain_plasti` and `materi_plasti_diprisco_history 11` should be initialized.

**6.697** **group\_materi\_plasti\_diprisco\_density** *index*  $\gamma_l$   $\hat{\beta}_{lf}$   $b_{lp}$   $c_{lp}$   $t_{lp}$   
 $\hat{\theta}_{lc}$   $\hat{\theta}_{le}$   $\xi_{lc}$   $\xi_{le}$   $\beta_{lf^0}$   $\gamma_d$   $\hat{\beta}_{df}$   $b_{dp}$   $c_{dp}$   $t_{dp}$   $\hat{\theta}_{dc}$   $\hat{\theta}_{de}$   $\xi_{dc}$   $\xi_{de}$   $\beta_{df^0}$   $e_l$   $e_d$

Yield data for di Prisco plasticity with varying density. All data with an  $l$  in the subscript holds for loose soil, whereas all data with an  $d$  in the subscript holds for dense soil. The actually used data will be interpolated between the loose and dense data using the current density.

The *index* specifies the `element_group`, see **element\_group**. Condition: **materi\_strain\_plasti** and **materi\_plasti\_diprisco\_history 12** should be initialized.

**6.698** **group\_materi\_plasti\_druck\_prag** *index*  $\phi$   $c$   $\phi_{flow}$

Both yield data and flow data (indicated by the word flow) for Drucker-Prager plasticity. Choose  $\phi$  and  $\phi_{flow}$  in between 0 and  $\frac{\pi}{2}$ . The *index* specifies the `element_group`, see **element\_group**. Condition: **materi\_strain\_plasti** should be initialized.

**6.699** **group\_materi\_plasti\_element\_group** *index*  $group\_0$   $group\_1$   
 $\dots$

With this record you can model frictional slip of soil material and alike granular materials on other materials like concrete, steel, etc.

This is done for **group\_materi\_plasti\_mohr\_coul**, **group\_materi\_plasti\_druck\_prag**, **group\_materi\_plasti\_hardsoil**, if specified, by reducing the friction angle  $\phi$  and dilatancy angle  $\phi_{flow}$  and cohesion  $c$  of the granular material with a factor (2./3.).

This is done for **group\_materi\_plasti\_camclay**, if specified, by reducing  $M$  with a factor (2./3.).

This is done for **group\_materi\_plasti\_tension**, if specified, by reducing  $sigy$  with a factor (2./3.).

This is done for **group\_materi\_plasti\_hypo\_\***, if specified, by reducing the deviatoric stress increments with a factor (2./3.).

With  $group\_0$  ,  $group\_1$  etc. you can specify the groups of the concrete material, steel material etc. The reduction of the friction angle and dilatancy angle will only be applied to the granular elements (of *element\_group*) which are a direct neighbor of an element which has one of the groups  $group\_0$  ,  $group\_1$  etc.

Please realise that this method only works well if the finite elements are not too large.

The *index* specifies the `element_group` of the granular material, see **element\_group**.

See also **group\_materi\_plasti\_element\_group\_factor**.

**6.700 group\_materi\_plasti\_element\_group\_factor** *index factor\_0 factor\_1 ...*

With this record you can specify a factor other than the default 2./3. used by the **group\_materi\_plasti\_element\_group\_factor** record. You need to specify a factor for each group.

As a special option you can specify one value only, which will then be used for all factors.

The *index* specifies the element\_group of the granular material, see **element\_group**.

**6.701 group\_materi\_plasti\_generalised\_non\_associate\_cam\_clay\_for\_bonded\_soils** *index ...*

Yield data for the Generalised Non Associate Cam Clay for Bonded Soils plasticity model. The *index* specifies the element\_group, see **element\_group**.

**6.702 group\_materi\_plasti\_gurson** *index sigy q1 q2 q3*

Yield data (also used as flow data) for Gurson plasticity. The *index* specifies the element\_group, see **element\_group**.

**6.703 group\_materi\_plasti\_hardsoil** *index  $\phi$   $c$   $\psi$   $R_f$*

Plasticity data for Hardening Soil model. The *index* specifies the element\_group, see **element\_group**.

This model requires sufficient small timesteps; in case of trouble try smaller timesteps.

**6.704 group\_materi\_plasti\_heat\_generation** *factor*

This *factor* specifies how much of the plastic energy loss is transformed into heat (this only makes sense if **condif\_temperature** is initialized). The *factor* should be between 0 and 1. The *index* specifies the element\_group, see **element\_group**.

#### 6.705 **group\_materi\_plasti\_hypo\_cohesion** *index c*

Cohesion parameter in hypoplastic law. First, the cohesion in this record is subtracted from the normal stresses in the hypo law evaluation, so that the hypo law is evaluated at a lower pressure level. Second, if the pressure level then still exceeds the  $-3.*c$ , the hypo law only will use its linear contribution. These actions increase numerical stability of the calculation in zones of small stresses (free surfaces).

The *index* specifies the element\_group, see **element\_group**.

#### 6.706 **group\_materi\_plasti\_hypo\_masin** *index $\varphi_c \lambda^* \kappa^* N r$*

Masin hypoplasticity parameters; see the theory section. The angle  $\varphi_c$  should be specified in degrees. The  $\lambda^*$  should be bigger than the  $\kappa^*$ .

#### 6.707 **group\_materi\_plasti\_hypo\_masin\_clay** *index $\varphi_c \lambda^* \kappa^* N \nu_{pp}$*

Masin clay hypoplasticity parameters. The angle  $\varphi_c$  should be specified in degrees. The  $\lambda^*$  should be bigger than the  $\kappa^*$ . Typical values are  $\varphi_c = 25$ ,  $\lambda^* = 0.1$ ,  $\kappa^* = 0.01$ ,  $N = 1$  and  $\nu_{pp} = 0.2$ .

#### 6.708 **group\_materi\_plasti\_hypo\_masin\_clay\_advanced\_parameters** *index $\alpha_G \alpha_f a_y o_c$*

Optional advanced parameters  $\alpha_G \alpha_f a_y o_c$  for masin lay law. If not specified the defaults are:  $\alpha_G = 1$ ,  $\alpha_f$  from governing equation in [13],  $a_y = 0.3$  and  $o_c = 2$ .

#### 6.709 **group\_materi\_plasti\_hypo\_masin\_clay\_avanced\_direction** *index $dir_i$*

Optional advanced integer parameter for Masin clay law. If not specified the default for the vertical direction  $dir_i$  is: 0 in 1D calculation, 1 in 2D calculation and 2 in 3D calculation.

#### 6.710 **group\_materi\_plasti\_hypo\_masin\_clay\_ocr** *index OCR*

OCR in masin hypoplastic law; the initial void ratio will be calculated from this. A typical value is  $OCR = 1.5$ . You need to set **control\_materi\_plasti\_hypo\_masin\_clay\_ocr\_apply** to **-yes**.

**6.711** `group_materi_plasti_hypo_masin_clay_structure` *index*  $k$   
 $A$   $s_f$

Masin clay hypoplasticity structure parameters; see the theory section. The  $k$  should be at least 0. The  $A$  should be greater or equal to 0, and lower than 1. The  $s_f$  should be greater or equal to 1. Typical values are  $k = 0.4$ ,  $A = 0.1$  and  $s_f = 1.5$ .

**6.712** `group_materi_plasti_hypo_masin_clay_visco` *index*  $D_r$   $I_v$

Masin clay hypoplasticity visco hypoplasticity parameters; see the theory section. Typical values are  $D_r = 1.e - 6$  and  $I_v = 0.1$ .

Remark: this law should not be combined with intergranular strains.

**6.713** `group_materi_plasti_hypo_masin_ocr` *index*  $OCR$

OCR in masin hypoplastic law; the initial void ratio will be calculated from this. You need to set `control_materi_plasti_hypo_masin_ocr_apply` to -yes.

**6.714** `group_materi_plasti_hypo_masin_structure` *index*  $k$   $A$   $s_f$

Masin hypoplasticity structure parameters; see the theory section. The  $k$  should be at least 0. The  $A$  should be greater or equal to 0, and lower than 1. The  $s_f$  should be greater or equal to 1.

**6.715** `group_materi_plasti_hypo_minimum_void_ratio` *index*  $minimum\_void\_ratio$

This option sets a minimum for the void ratio as calculated by hypoplasticity laws. If the void ratio would become lower than this *minimum\_void\_ratio* value it will be reset to this *minimum\_void\_ratio* value.

This option becomes handy when in difficult nonlinear calculations the void ratio may become negative in local zones, preventing the remainder of the calculation to continue. You should check the final results of the calculation if they are what you want.

The *index* specifies the element\_group, see `element_group`.

**6.716** `group_materi_plasti_hypo_strain_intergranular` *index*  $R$   $m_R$   
 $m_T$   $\beta_r$   $\chi$   $\theta$

Intergranular strain parameters in hypoplastic law. The *index* specifies the `element_group`, see **element\_group**.

**6.717** `group_materi_plasti_hypo_strain_intergranular_masin_clay`  
*index*  $\bar{R}$   $A_g$   $n_g$   $m_{rat}$   $\beta_r$   $\chi$   $\theta$

Intergranular strain parameters for masin clay hypoplastic law. Typical values are  $R = 5.e - 5$ ,  $A_g = 270$ ,  $n_g = 1$ ,  $m_{rat} = 0.5$ ,  $\beta_r = 0.08$ ,  $\chi = 7$  and  $\theta = 7$ . The *index* specifies the `element_group`, see **element\_group**.

**6.718** `group_materi_plasti_hypo_strain_isa` *index*  $\chi_{\max}$   $C_a$

ISA-Intergranular strain parameters in hypoplastic law; see the theory section. The *index* specifies the `element_group`, see **element\_group**.

**6.719** `group_materi_plasti_hypo_wolffersdorff` *index*  $\varphi$   $h_s$   $n$   $e_{c0}$   $e_{d0}$   
 $e_{i0}$  *alpha* *beta*

Von-Wolffersdorff parameters in hypoplastic law; see the theory section. Here  $\varphi$  is in degrees. The *index* specifies the `element_group`, see **element\_group**.

**6.720** `group_materi_plasti_hypo_wolffersdorff_niemunis` *index*  $\nu$   
 $z$

Von-Wolffersdorff-Niemunis extended parameters in hypoplastic law; see the theory section. The *index* specifies the `element_group`, see **element\_group**.

**6.721** `group_materi_plasti_hypo_niemunis_visco` *index*  $\varphi$   $\nu$   $D_r$   
 $I_v$   $e_{e0}$   $p_{e0}$  *lambda*  $\beta_R$  *kappa*

Parameters  $\varphi$   $\nu$   $D_r$   $I_v$   $e_{e0}$   $p_{e0}$   $\lambda$   $\beta_R$   $\kappa$  for the visco part of hypoplasticity; see the theory section.

The history variables are the same as for `group_materi_plasti_hypo_wolffersdorff`. You also need to specify `control_materi_plasti_hypo_niemunis_visco_ocr_apply`.

The *index* specifies the `element_group`, see **element\_group**.

### 6.722 **group\_materi\_plasti\_hypo\_niemunis\_visco\_ocr** *index OCR*

OCR in visco hypoplastic law. The initial void ratio will be calculated from this; see the theory section.

In case you would like to have an OCR dependent on space coordinate you can use **dependency\_diagram** and **dependency\_item**.

The *index* specifies the **element\_group**, see **element\_group**.

### 6.723 **group\_materi\_plasti\_hypo\_void\_ratio\_linear** *index switch*

Normally the void ratio change in hypoplasticity is calculated by using the trace of the deformation tensor. That in fact uses a linear approximation of the volume change. This linear approximation is convenient to compare results with analytical theories which are based on such linear approximation, and also to use parameters in hypoplastic laws which are calibrated with such approximation.

Optionally, using **-no** in this **group\_materi\_plasti\_hypo\_void\_ratio\_linear** record, the exact volume change of the material is calculated using the determinant of the deformation tensor, and used to calculate the exact new void ratio. However, hypoplasticity laws are usually fitted on the linear approximation of the volume change. So you should not use **-no** unless you are perfectly certain what you are doing.

### 6.724 **group\_materi\_plasti\_kinematic\_hardenig** *index a*

This record specifies the size of the rate of the kinematic hardening matrix  $\rho_{ij}$ . The *index* specifies the **element\_group**, see **element\_group**.

### 6.725 **group\_materi\_plasti\_mohr\_coul** *index phi c phiflow*

Both yield data and flow data (indicated by the word flow) for Mohr-Coulomb plasticity. Choose *phi* and *phiflow* in between 0 and  $\frac{\pi}{2}$ . The *index* specifies the **element\_group**, see **element\_group**.

It is advised to use **group\_materi\_plasti\_tension** or preferably with **group\_materi\_plasti\_tension\_direct** for tension cutoff of large tension stresses.

### 6.726 **group\_materi\_plasti\_mohr\_coul\_direct** *index phi c phiflow*

Both yield data and flow data (indicated by the word flow) for Mohr-Coulomb plasticity. Choose *phi* and *phiflow* in between 0 and  $\frac{\pi}{2}$ . The *index* specifies the **element\_group**, see

**element\_group.**

Principal stress differences higher than allowed by the mohr-coulomb criterium are not allowed and will be cut of by Tochnog. This model uses an alternative programming of the mohr-coulomb law, which tends to be very stable.

You must specify also **group\_materi\_plasti\_tension\_direct**.

You can apply softening with a **dependency\_diagram** on **materi\_strain\_total\_shear\_kappa**.

#### 6.727 **group\_materi\_plasti\_mohr\_coul\_direct\_normal** *index normal\_x normal\_y normal\_z*

This option i.c.w. **group\_interface\_materi\_plasti\_mohr\_coul\_direct** ensures that the friction stress does not exceed the mohr coulomb shear stress limit on specifically the plane with normal vector *normal\_x normal\_y normal\_z*. In 1d only specify *normal\_x*, etc.

If this option is used i.c.w. **group\_materi\_plasti\_element\_group** or **group\_materi\_plasti\_bounda** it will only be actually used in elements with satisfy the condition listed in **group\_materi\_plasti\_element\_group** or **group\_materi\_plasti\_bounda**.

To limit tension stress on specifically the plane with a normal vector use **group\_materi\_plasti\_tension\_direct\_normal**.

#### 6.728 **group\_materi\_plasti\_mohr\_coul\_direct\_normal\_automatic** *index switch*

This option is similar to **group\_materi\_plasti\_mohr\_coul\_direct\_normal**, however now the normal direction is automatically taken from the element normal **element\_normal**. You need to set *switch* to **-yes**.

#### 6.729 **group\_materi\_plasti\_mohr\_coul\_direct\_visco** *index tm*

Characteristic relaxation time for visco plasticity with **group\_materi\_plasti\_mohr\_coul\_direct**. Choose *tm* small if you want to have fast relaxation of the plasticity to the plastic state.

Thus the **group\_materi\_plasti\_mohr\_coul\_direct** can only use this **group\_materi\_plasti\_mohr\_coul** for visco-plasticity, and no other visco-plasticity model.

For **group\_materi\_plasti\_...\_direct\_visco** laws visco plasticity works as follows. Suppose the stress at time  $t$  is  $\sigma_t$ . Calculate the elastic response (non-plastic) at time  $t + dt$  as  $\sigma_{e,t+dt}$ . Calculate the plastic non-viscous response at time  $t + dt$  as  $\sigma_{p,t+dt}$ . Calculate the plastic viscous response at time  $t + dt$  as

$$\sigma_{vp,t+dt} = \sigma_{e,t+dt} + factor * (\sigma_{p,t+dt} - \sigma_{e,t+dt})$$

where

$$factor = 1 - \exp(-dt/tm)$$

Notice that for  $dt$  is very small  $factor = 0$  so  $\sigma_{vp,t+dt} = \sigma_{e,t+dt}$ , thus purely elastic response (which is the stress at the previous time plus the elastic stress increment). Notice that for  $dt$  is very large  $factor = 1$  so  $\sigma_{vp,t+dt} = \sigma_{p,t+dt}$ , thus purely plastic response (which is the stress completely mapped to the plastic surface). And for  $dt$  in between the response is in between the elastic response and purely plastic response.

### 6.730 **group\_materi\_plasti\_mohr\_coul\_direct\_wall** *index phi c phi-flow*

As a special option for **group\_materi\_plasti\_mohr\_coul\_direct** you can use a record **group\_materi\_plasti\_mohr\_coul\_direct\_wall** *index phi c phiflow*. These values will be used when an element is attached to a wall. The input file needs to contain **group\_materi\_plasti\_element\_group**, **group\_materi\_plasti\_bounda** or **group\_materi\_plasti\_mpc** to specify when an element is at the wall. Thus a typical input file looks like:

```
...
group_materi_plasti_mohr_coul_direct 0 ... (values for elements not
attached to wall)
group_materi_plasti_mohr_coul_direct_wall 0 ... (values for ele-
ments attached to wall)
group_materi_plasti_mpc 0 -yes (elements with mpc's are attached to
wall)
...
end_data
```

See also **group\_materi\_plasti\_element\_group**, **group\_materi\_plasti\_bounda** and **group\_materi\_plasti\_mpc**.

### 6.731 **group\_materi\_plasti\_mohr\_coul\_hardening\_softening** *index phi\_0 c\_0 phiflow\_0 phi\_1 c\_1 phiflow\_1 kappashear\_crit*

Both yield data and flow data (indicated by the word flow) for Mohr-Coulomb hardening-softening plasticity. See the theoretical part. Choose each of the angles  $\phi_0$  *phiflow\_0*  $\phi_1$  *phiflow\_1* in between 0 and  $\frac{\pi}{2}$ . It is advised to use **group\_materi\_plasti\_tension** or preferably with **group\_materi\_plasti\_tension\_direct** for tension cutoff of large tension stresses. The *index* specifies the element\_group, see **element\_group**.

### 6.732 **group\_materi\_plasti\_mohr\_coul\_direct\_wall** *index phi c phi-flow*

As a special option for **group\_materi\_plasti\_mohr\_coul\_direct** you can use a record **group\_materi\_plasti\_mohr\_coul\_direct\_wall** *index phi c phiflow*. These values will be used when an element is attached to a wall. The input file needs to contain **group\_materi\_plasti\_bounda** or **group\_materi\_plasti\_mpc** to specify when an element is at the wall. Thus a typical input file looks like:

```
...
group_materi_plasti_mohr_coul_direct 0 ... (values for elements not
attached to wall)
group_materi_plasti_mohr_coul_direct_wall 0 ... (values for ele-
ments attached to wall)
group_materi_plasti_mpc 0 -yes (elements with mpc's are attached to
wall)
...
end_data
```

See also **group\_materi\_plasti\_bounda** and **group\_materi\_plasti\_mpc**.

### 6.733 **group\_materi\_plasti\_mpc** *index switch*

Same as **group\_materi\_plasti\_bounda**, but now for **mpc** ... records however. If you set *switch* to **-yes**, the reduction factor will be applied if there is any mpc at the node of an element.

See also **group\_materi\_plasti\_mpc\_factor**.

### 6.734 **group\_materi\_plasti\_mpc\_factor** *index factor*

Same as **group\_materi\_plasti\_bounda\_factor**, but now for **group\_materi\_plasti\_mpc** however.

### 6.735 **group\_materi\_plasti\_pressure\_limit** *index pressure\_limit*

To prevent plasticity problems near free surfaces, you can require that Tochnog neglects plasticity laws if the pressure exceeds *pressure\_limit*. This option is not available for hypoplasticity laws, since for these laws nonlinear elasticity and plasticity are defined by one law, so the plasticity part cannot be suppressed by itself.

See also **group\_materi\_plasti\_pressure\_limit\_method**.

### 6.736 **group\_materi\_plasti\_residual\_stiffness** *index factor*

With *factor* you can set the part of the original shear stiffness to be used as stiffness in plastic elementss. Default, if this record is not specified, the *factor* is set to 1.

### 6.737 **group\_materi\_plasti\_tension** *index sigy*

Yield data for tension plasticity. The *index* specifies the **element\_group**, see **element\_group**. Condition: **materi\_strain\_plasti** should be initialized.

It is encouraged to use **group\_materi\_plasti\_tension\_direct** instead, which tends to give more stable calculations.

### 6.738 **group\_materi\_plasti\_tension\_direct** *index sigy*

Tension limit. Principal stresses higher than *sigy* are not allowed and will be cut of by Tochnog. This model uses directly a cut-off of stresses, and does not use plastic strains. The *index* specifies the **element\_group**, see **element\_group**.

If this option is not specified *sigy* is set to 0 if also the **group\_materi\_plasti\_mohr\_coul\_direct** is available for the group.

You can apply softening with a **dependency\_diagram** on **materi\_strain\_total\_tension\_kappa**.

### 6.739 **group\_materi\_plasti\_tension\_direct\_normal** *index normal\_x normal\_y normal\_z*

This option i.c.w. **group\_materi\_plasti\_tension\_direct** limits the tension stress specifically on specifically the plane specified by the normal *index normal\_x normal\_y normal\_z*. In 1D only *normal\_x* should be specified etc.

If this option is used i.c.w. **group\_materi\_plasti\_element\_group** or **group\_materi\_plasti\_bounda** it will only be actually used in elements with satisfy the condition listed in **group\_materi\_plasti\_element\_group** or **group\_materi\_plasti\_bounda**.

### 6.740 **group\_materi\_plasti\_tension\_direct\_normal\_automatic** *index switch*

This option is similar to **group\_materi\_plasti\_tension\_direct\_normal**, however now the normal direction is automatically taken from the element **element\_normal**. You need to set *switch* to **-yes**.

#### 6.741 **group\_materi\_plasti\_tension\_direct\_visco** *index tm*

Characteristic relaxation time for visco plasticity with **group\_materi\_plasti\_tension\_direct**. Choose *tm* small if you want to have fast relaxation of the plasticity to the plastic state.

Thus the **group\_materi\_plasti\_tension\_direct** can only use this **group\_materi\_plasti\_tension\_direct** for visco-plasticity, and no other visco-plasticity model.

See also **group\_materi\_plasti\_mohr\_coul\_direct\_visco**.

#### 6.742 **group\_materi\_plasti\_tension\_direct\_wall** *index sigy*

As a special option for **group\_materi\_plasti\_tension\_direct** you can use a record **group\_materi\_plasti\_tension\_direct\_wall** *index sigy*. This value will be used when an element is attached to a wall. The input file needs to contain **group\_materi\_plasti\_element\_group**, **group\_materi\_plasti\_bounda** or **group\_materi\_plasti\_mpc** to specify when an element is at the wall.

#### 6.743 **group\_materi\_plasti\_user** *index switch*

If *switch* is set to **-yes** the user supplied routine for plasticity is called.

See also the file **user.cpp** in the distribution.

The *index* specifies the **element\_group**, see **element\_group**.

#### 6.744 **group\_materi\_plasti\_visco\_exponential** *index $\gamma$ $\alpha$*

This record specifies visco-plasticity data for the exponential model. It should be used in combination with a plasticity model.

#### 6.745 **group\_materi\_plasti\_visco\_exponential\_limit** *index limit*

This record defines the limit for the exponential viscoplasticity argument *alpha f*. If the argument *alpha f* becomes larger than *limit* then actually *limit* will be used instead as argument for the exponent.

Default, if **group\_materi\_plasti\_visco\_exponential\_limit** is not specified, then 3 will be used as limit.

This record specifies visco-plasticity data for the exponential model. It should be used in combination with a plasticity model.

**6.746** `group_materi_plasti_visco_exponential_name` *index* *name\_0*  
*name\_1* ...

Same as `group_materi_plasti_visco_power_names`, now for the exponential law however.

**6.747** `group_materi_plasti_visco_exponential_values` *index*  $\gamma_0$   $\alpha_0$   
 $\gamma_1$   $\alpha_1$  ...

See `group_materi_plasti_visco_exponential_name`.

**6.748** `group_materi_plasti_visco_power` *index*  $\eta$   $p$

This record specifies visco-plasticity data for the power model. It should be used in combination with a plasticity model.

The *index* specifies the `element_group`, see `element_group`.

**6.749** `group_materi_plasti_visco_power_name` *index* *name\_0* *name\_1*  
...

This `group_materi_plasti_visco_power_name` together with `group_materi_plasti_visco_power_value` allows you to specify different viscoelastic parameters for each of the plasticity models.

Set each of the names *name\_0* , *name\_1* , etc. to the plasticity models that you use (eg `-group_materi_plasti_mohr_coul` etc.) Set the visco parameters for *name\_0* in  $\eta_0$  and  $p_0$  , set the visco parameters for *name\_1* in  $\eta_1$  and  $p_1$  , etc.

In case a plasticity model is used, but is not present in the names *name\_0* , *name\_1* , etc. then that model will be evaluated elasto-plastic (and thus not elasto-viscoplastic).

The *index* specifies the `element_group`, see `element_group`.

**6.750** `group_materi_plasti_visco_power_value` *index*  $\eta_0$   $p_0$   $\eta_1$   $p_1$   
...

See `group_materi_plasti_visco_power_name`.

### 6.751 **group\_materi\_plasti\_vonmises** *index sigma<sub>y0</sub>*

Yield data for Von-Mises plasticity.

The *index* specifies the element\_group, see **element\_group**. Condition: **materi\_strain\_plasti** should be initialized.

### 6.752 **group\_materi\_plasti\_vonmises\_nadai** *index C κ<sub>0</sub> n*

Data for Von-Mises Nadai hardening. The *sigma<sub>y0</sub>* of the **group\_materi\_plasti\_vonmises** record is taken as *sigma<sub>y0</sub>* in the nadai law.

The *index* specifies the element\_group, see **element\_group**. Condition: **materi\_plasti\_kappa** should be initialized.

### 6.753 **group\_materi\_stokes** *index switch*

If *switch* is set to **-yes**, then stokes flow is used. If *switch* is set to **-no**, then stokes flow is not used. Default it is set to **-yes**. The *index* specifies the element\_group, see **element\_group**.

### 6.754 **group\_materi\_stress\_null** *index dir ...*

With this option you can set the stress in the material in direction *dir* to zero. For *dir* you can use each of the local directions **-x**, **-y**, **-z** or the local shear directions **-xy**, **-xz**, **-yz**. You can specify multiple directions, for example **group\_materi\_stress\_null index -y -z**.

With **group\_materi\_stress\_null\_direction** you can specify local frame directions (nine values) **-x**, **-y**, **-z**. Take care that these directions are perpendicular and of unit length.

If **group\_materi\_stress\_null\_direction\_automatic** is specified, the local frame **-x**, **-y**, **-z** is made out of the element normal direction **element\_normal** and two directions perpendicular to it.

If **group\_materi\_stress\_null\_direction** and **group\_materi\_stress\_null\_direction\_automatic** are not specified, the global frame is used as local frame.

### 6.755 **group\_materi\_stress\_null\_direction** *index dir0\_x dir0\_y dir0\_z dir1\_x dir1\_y dir1\_z dir2\_x dir2\_y dir2\_z*

See **group\_materi\_stress\_null**.

#### 6.756 `group_materi_stress_null_direction_automatic` *switch*

See `group_materi_stress_null`.

#### 6.757 `group_materi_umat` *index switch*

If *switch* is set to **-yes** then the user supplied umat routine is called for the element group *index*.

See also the section about user supplied routines at the end of this manual.

#### 6.758 `group_materi_umat_parameters` *index parameter\_0 parameter\_1 ...*

User supplied parameters for `group_materi_umat`.

#### 6.759 `group_materi_umat_pardiso_decompose` *index switch*

If *switch* is set to **-yes** and an umat routine is present, Tochnog will ask the pardiso solver to decompose the system matrix each and every iteration of each and every timestep. If *switch* is set to **-no** and an umat routine is present, Tochnog will ask the pardiso solver to decompose the system matrix only once (please realise, however, that because of other input file options the decomposition possibly can be done more than once). Default, if *switch* is not defined, it is set to **-yes**.

#### 6.760 `group_materi_undrained_capacity` *index C*

Capacity for undrained analysis. See the theory section for details on undrained analyses.

#### 6.761 `group_materi_viscosity` *index $\nu$*

Dynamic viscosity for nearly incompressible Newtonian flow. The *index* specifies the element\_group, see `element_group`.

#### 6.762 `group_materi_viscosity_heatgeneration` *index switch*

If *switch* is set to **-yes**, then viscous dissipation will be used as a heat generation source. See also the theoretical part at the start of this manual. The *index* specifies the element\_group, see `element_group`.

### 6.763 **group\_plasti\_apply** *index switch*

If *switch* is set to **-no** any plasticity data in the group *index* will be neglected. Default, if **group\_plasti\_apply** is not specified, *switch* is set to **-yes**.

### 6.764 **group\_porosity** *index n*

Porosity in material. For example needed for **group\_groundflow\_nonsaturated\_vangenuchten**. The *index* specifies the *element\_group*, see **element\_group**.

### 6.765 **group\_spring\_direction** *index dir\_x dir\_y dir\_z*

Direction of a spring. If for a **-spring2** this record is not specified, the direction is taken to be from the first node of the spring to the second node. The *index* specifies the *element\_group*, see **element\_group**.

### 6.766 **group\_spring\_memory** *index memory\_type*

Memory model for spring; either **-updated\_linear**, **-total\_linear** or **-updated**. The **-updated** model is a geometrically nonlinear model which takes large spring rotations into account for two-noded springs. The *index* specifies the *element\_group*, see **element\_group**.

### 6.767 **group\_spring\_plasti** *index F<sub>y</sub>*

Maximum force in a spring. The *index* specifies the *element\_group*, see **element\_group**.

### 6.768 **group\_spring\_stiffness** *index k*

Stiffness of a spring. It is multiplied with the elongation of the spring to calculate the spring force. The *index* specifies the *element\_group*, see **element\_group**.

### 6.769 **group\_spring\_stiffness\_nonlinear** *index epsilon<sub>0</sub> k<sub>0</sub> epsilon<sub>1</sub> k<sub>1</sub> ...*

Diagram with spring stiffness dependent on total spring strain (= total spring elongation). Here *epsilon<sub>0</sub>* *k<sub>0</sub>* is the first point in the diagram, with *epsilon<sub>0</sub>* the total spring strain and *k<sub>0</sub>* the spring stiffness. Likewise for the next points in the diagram. Take care that you

specify diagram values with a strain range that includes all spring strain that actually occur in the calculation.

The *index* specifies the element\_group, see **element\_group**.

### **6.770** group\_time *index birth death*

With this option you can set the time of birth of the elements (in group *index*) and the time of death of the elements.

Out of the range *birth* - *death* the elements of the group will not be used in the calculation (the starting *birth* limit itself is not included in the range, whereas the ending *death* limit itself is included).

### **6.771** group\_time\_fill *index birth\_empty birth\_filled death*

With this option you can set the time of birth of the elements (in group *index*) and the time of death of the elements.

Out of the range *birth\_empty* - *death* the elements of the group will not be used in the calculation (the starting *birth\_empty* limit itself is not included in the range, whereas the ending *death* limit itself is included).

Between *birth\_empty* and *birth\_filled* the elements will be 'slowly filled with material'. This means that the density of the element and the total pressure (pore pressure), in case groundflow is present, will be scaled with a factor 0 at time *birth\_empty* up to a factor 1 at time *birth\_filled*. To prevent numerical problems at low gravity, any plasticity data will be ignored when an element is being filled; after the element is completely filled plasticity will become active (plasticity data will be applied).

### **6.772** group\_truss\_area *index A*

Cross-sectional area for a truss. The *index* specifies the element\_group, see **element\_group**.

### **6.773** group\_truss\_density *index $\rho$*

Density for a truss. The *index* specifies the element\_group, see **element\_group**.

**6.774 group\_truss\_elasti\_elongation\_force\_diagram** *index l\_0 F\_0 l\_1 F\_1 ...*

With this record you can specify a force versus elongation diagram for a truss. Here each  $l_i$  is the ratio of the truss elongation divided by the initial truss length. And each  $F_i$  is the corresponding force. This **group\_truss\_elasti\_elongation\_force\_diagram** cannot be combined with **group\_truss\_elasti\_young**.

**6.775 group\_truss\_elasti\_young** *index E*

Young's modulus for a truss. The truss force  $F$  is  $F = EA\Delta u$ , where  $\Delta u$  is the elongation of the truss. The *index* specifies the element\_group, see **element\_group**.

See also **group\_truss\_area**.

**6.776 group\_truss\_expansion** *index alpha*

Thermal expansion coefficient for trusses. A temperature increment  $dT$  leads to a thermal incremental length of the size  $\alpha * dT * \text{initial length}$ ;

**6.777 group\_truss\_initial\_force** *index initial\_force*

Initial truss force in truss elements.

**6.778 group\_truss\_memory** *index memory\_type*

Memory model for truss; either **-updated\_linear**, **-updated** or **total\_linear**. The **-updated** model is a geometrically nonlinear model which takes large truss rotations into account. The *index* specifies the element\_group, see **element\_group**.

**6.779 group\_truss\_rope** *index switch*

The truss will act as a rope if *switch* is set to **-yes**. This means that negative forces will not be allowed (the force remains zero in compression). The *index* specifies the element\_group, see **element\_group**.

#### 6.780 **group\_truss\_plasti** *index sigma<sub>c</sub> sigma<sub>t</sub>*

Compressive and tension yield stress for truss. The actual stress cannot become lower than the  $\sigma_c$  in compression, and the actual stress cannot become higher than the  $\sigma_t$  in tension. The *index* specifies the element\_group, see **element\_group**.

#### 6.781 **group\_type** *index type\_name\_0 type\_name\_1 ...*

With this record a differential equation is specified for the element group *index*. Allowed type names are **-condif**, **-groundflow**, **-materi**, **-wave**, **-spring**, **-contact\_spring**, **-truss**, **-beam**, **-truss\_beam**. Also **-empty** is allowed; it indicates that the element is empty.

For the **-truss\_beam** type you need to set parameters with **group\_truss\_\*** and **group\_beam\_\*** records. For the **-truss** type you need to set parameters with **group\_truss\_\*** records. For the **-beam** type you need to set parameters with **group\_beam\_\*** records. For the **-condif** type you need to set parameters with **group\_condif\_\*** records. For the **-materi** type you need to set parameters with **group\_materi\_\*** records. Etc etc.

See also **element\_group**.

#### 6.782 **group\_volume\_factor** *index factor*

In 1D or 2D you can specify the cross-section and thickness respectively, for elements of the element group *index* (see **element\_group**).

See also **volume\_factor**.

#### 6.783 **group\_wave\_speed\_of\_sound** *index c*

Speed of sound in wave equation. The *index* specifies the element\_group, see **element\_group**.

#### 6.784 **icontrol** *icontrol*

With this record you can set the control index which already have been performed. Thus if you set it to 10, all **control\_\*** records up to and including those with index 10 will be skipped, and the control indices starting from 11 will be performed.

#### 6.785 **incremental\_driver** ...

All incremental driver options are given in the example input file below:

```

echo -no
number_of_space_dimensions 2
materi_velocity
materi_velocity_integrated
materi_strain_total
materi_strain_plasti
materi_strain_intergranular
materi_strain_isa_c
materi_strain_isa_eacc
materi_plasti_hypo_history 4
materi_stress
groundflow_pressure
end_initia

```

( RUNNING:

Run this file with the normal tochnog executable.  
Results are written in incremental\_driver\_result.txt.

EQUILIBRIUM:

At the start equilibrium is assumed (an external force is assumed which makes equilibrium with the internal stress and internal pore water pressure if specified).

UNITS:

The word force below means a force unit (eg kN).  
The word stress below means a stress unit (eg kPa).  
The incremental driver does not use specific units; all units can be used which are consistent. As an exception the hypoplastic masin law uses specific units (see the tochnog users manual).

EXPERIMENTS:

-INCREMENTAL\_DRIVER\_OEDOMETRIC

'group\_axisymmetric index -yes' is allowed; then x=r and y=theta.  
'incremental\_driver\_volume\_constant index -yes' is not allowed  
x: zero displacement in x-direction  
y: zero displacement and strain in y-direction  
z: compression in z-direction  
user specified: displacement or force on top plane in z-direction,  
the specified values should be negative for compression

-INCREMENTAL\_DRIVER\_TRIAX

'group\_axisymmetric index -yes' is allowed; then x=r and y=theta.  
'incremental\_driver\_volume\_constant index -yes' is allowed;  
then the volume is kept constant (undrained water pressure is not needed)  
x: fixed stress in x-direction  
y: if axisymmetric then y-strain comes from calculation,  
if not axisymmetric then constant stress in y direction

z: compression in z-direction  
user specified: displacement or force on top plane in z-direction,  
the specified values should be negative for compression

**-INCREMENTAL\_DRIVER\_DIRECT\_SHEAR**

'group\_axisymmetric index -yes' is not allowed.  
'incremental\_driver\_volume\_constant index -yes' is allowed;  
then the volume is kept constant (undrained water pressure is not needed)  
x: zero strain in x-direction  
y: zero displacement and strain in y-direction  
z: shear of top z-plane in x-direction, fixed stress in z-direction  
user specified: shear displacement or shear force on top plane in x-direction

**-INCREMENTAL\_DRIVER\_HYDROSTATIC**

'group\_axisymmetric index -yes' is allowed.  
'incremental\_driver\_volume\_constant index -yes' is not allowed  
equal compression in x- and y- and z-direction  
user specified: volumetric displacement  
( (x- plus y- plus z-displacement ) / 3. ) or volumetric stress  
notice: not a force but instead a stress is specified.

**COMBINED EXPERIMENTS:**

Only combined experiments will be analysed, and only output will be printed for these combined experiments; the experiments by themselves will not be analysed. The start time of each experiment in a combined experiment should be equal to the end time of a previous experiment in that combined experiment. Only for the first experiment the variables incremental\_driver\_void\_ratio, incremental\_driver\_stress ,incremental\_driver\_pressure and incremental\_driver\_intergranular\_strain can be specified; for all subsequent experiments these values will be taken from the end values of the previous experiment. If no combined experiments are specified, automatically a combined experiment will be generated for each experiment, containing that experiment only. Notice that prescribed displacements and forces in an experiment are additional to the last values of the previous experiment. In an experiment all forces that are not prescribed and don't belong to a prescribed displacement remain equal to those of the previous experiment.

**UNDRAINED:**

You can obtain undrained behavior in two different ways:

1. Use groundwater in the test specimen. The groundwater capacity physically causes the test specimen to behave undrained.
  2. Apply 'incremental\_driver\_volume\_constant index -yes' . This causes the deformations of the test specimen to be such that the volume remains constant.
- You should choose one of both methods. You should not combine both methods.

**GROUNDFLOW:**

In case of 'group\_type index -groundflow' groundwater is present in the test specimen.

Then all groundflow initialisation and data needs to be specified (search for groundflow in this file to see what is needed).

#### MATERIAL LAWS:

group\_materi\_plasti\_mohr\_coul\_direct\*  
group\_materi\_plasti\_hypo\*  
group\_materi\_umat\*  
See the tochnog users manual.

#### MATERIAL MEMORY:

If you use -updated\_linear then small deformation theory is used, and the area change of the surface where forces are applied is not taken into account.  
If you use -updated\_area then small deformation theory is used, but the area change of the surface where forces are applied is taken into account.  
If you use -updated then large deformation theory is used, and the area change of the surface where forces are applied is taken into account.

#### AXISYMMETRIC:

Either all experiments are axisymmetric or all experiments are not axisymmetric.  
Do not mix axisymmetric and non-axisymmetric experiments in a combined experiment.

)

### 6.786 inertia\_apply switch\_0 switch\_1 ...

If *switch\_0* is set to **-yes**, the corresponding inertia term is included (material mass, heat capacity, ..). The same for the other switches. A switch should be specified for each of the principal dof's. See the 'input file - data part - introduction - types of dof's' section for an explanation about principal dof's. The sequence of the principal dof's is in the order as initialised in the **initia ... end\_initia** part.

As a special option you can specify only one switch, and then the specified value will automatically be used for all principal dof's.

This **inertia\_apply** is applied for all timestep records.

Default, if **inertia\_apply** is not specified, then each of *switch\_0*, *switch\_1* etc. is set to **-no**.

See also **control\_inertia\_apply**.

### 6.787 input\_abaqus switch

Set *switch* to **-yes** for reading the abaqus input file **abaqus.inp**. Tochnog will use it to generate a tochnog input file **tochnog\_abaqus.dat**. This can typically be done by making an input file like:

```
...
echo -yes
number_of_space_dimensions 3
materi_velocity
materi_stress
end_initia
input_abaqus -yes
input_abaqus_mesh -no
input_abaqus_continue -yes
...
include tochnog_abaqus.dat
...
( other data , you can use the abaqus sets of tochnog_abaqus.dat )
...
end_data
```

You need to initialise the fields like **materi\_velocity**, **materi\_stress**, etc that you will

actually use later in the calculation. Only a limited set of data is transferred from the abaqus input file to the tochnog input file; you need to check if the Tochnog input file is like you want. Abaqus element sets and node sets are evaluated and can be used in the tochnog calculation.

ABAQUS is a registered trademark or trademark of Dassault Systemes. Abaqus input files can be generated by many programs, among which **mecway** is relatively affordable, see <https://mecway.com/> .

### 6.788 input\_\_abaqus\_\_continue *switch*

If *switch* is set to **-yes** then after **tochnog\_\_abaqus.dat** is generated the remainder of the input file read and the calculation continues. If *switch* is set to **-no** then after **tochnog\_\_abaqus.dat** is generated the remainder of the input file will not be read and the calculation aborts. The **input\_\_abaqus\_\_continue** record should always be present as last record of the **input\_\_abaqus\_\_\*** records.

### 6.789 input\_\_abaqus\_\_group *switch*

If *switch* is set to **-yes** then also **group\_\_\*** is written to **tochnog\_\_abaqus.dat**. If *switch* is set to **-no** then no **group\_\_\*** is written to **tochnog\_\_abaqus.dat**. So you can set *switch* to **-no** in case you want to provide the **group\_\_\*** yourself, and don't want it to be taken from the **abaqus.inp**.

Default, if **input\_\_abaqus\_\_group** is not specified, the *switch* is set to **-yes**.

### 6.790 input\_\_abaqus\_\_mesh *switch*

If *switch* is set to **-no** then only mesh data is written to **tochnog\_\_abaqus.dat**; so timestep information and post processing prints are not written. This record should be placed before the **input\_\_abaqus\_\_continue** record.

Default the *switch* is set to **-no**.

### 6.791 input\_\_abaqus\_\_set *set\_0 set\_1 ...*

With this option you can specify for which set numbers the elements should be written. See the generated **tochnog\_\_abaqus.dat** for the set numbers.

### 6.792 `input__abaqus__name` *name\_0 name\_1 ...*

With this option you can specify which abaqus element types should be converted into tochnog elements. For example specify **-tria3** if you want to include **tria3** elements in the Tochnog input file. In case you do not specify **input\_\_abaqus\_\_name** all elements will be converted into tochnog elements. However, not all abaqus elements are available as tochnog element; if a non-available element is encountered it will be skipped.

### 6.793 `input__feflow__mesh` *switch*

If *switch* is set to **-yes** the mesh is read from a FEFLOW file. FEFLOW is a dedicated groundwater analysis program, see <https://www.mikepoweredbydhi.com/products/feflow>. The Tochnog input file itself should not contain a mesh (elements and nodes). Presently, in a 3D analysis the thickness of each layer should be uniform over the nodes (no varying layer thickness in x- and y-direction). Default elements of the FEFLOW file get the **element\_group** 0 in the Tochnog calculation; however, for each set of elements specified inside the feflow file with **K\_xx** inside **MAT\_I\_FLOW** an increasing element group number is generated (1 for the elements specified in the first **K\_xx**, 2 for the elements specified in the second **K\_xx**, etc.).

### 6.794 `input__feflow__fem` *switch*

If the *switch* in **input\_\_feflow\_\_fem** is set to **-yes** the mesh is read from the file **feflow.fem**. If the *switch* in **input\_\_feflow\_\_fem** is set to **-no** the mesh is read from the file **feflow.dac**. Both files should be in ASCII text format. Default, if **input\_\_feflow\_\_fem** is not specified, the *switch* is set to **-no**.

See also **input\_\_feflow\_\_mesh**.

### 6.795 `input__feflow__mesh__hydraulic__head` *switch*

If the *switch* in **input\_\_feflow\_\_hydraulic\_\_head** is set to **-yes** then also the hydraulic head is read from the **feflow.dac** file. The **feflow.dac** should contain hydraulic pressure head results for all time points in the Tochnog calculation. The hydraulic pressure head as calculated by FEFLOW is then used as prescribed value in the Tochnog calculation, so that Tochnog only calculates stress (influenced however by the presence of the hydraulic pressure head). This option allows you to calculate hydraulic safety factors using FEFLOW hydraulic pressure heads and Tochnog stresses (see **safety\_\_piping** and **safety\_\_lifting** in **post\_\_calcul**).

See also **input\_\_feflow\_\_mesh**.

### 6.796 input\_gmsh *switch*

Set *switch* to **-yes** for reading the **gmsh** mesh file **tochnog\_in.msh**. Only linear and quadratic elements are read.

The **gmsh** program is a free external pre- and postprocessor. See <http://www.geuz.org/gmsh>.

Only the data **element**, **element\_group** and **node** is read.

### 6.797 interface\_gap\_apply *switch*

If *switch* is set to **-yes** then any **group\_interface\_gap** will be applied. If *switch* is set to **-no** then any **group\_interface\_gap** will be ignored.

Default, if **interface\_gap\_apply** is not specified, *switch* is set to **-yes**.

This **interface\_gap\_apply** record will be overruled by the **control\_interface\_gap\_apply** record if specified.

### 6.798 linear\_calculation\_apply *switch*

If you set the *switch* to **-yes**, Tochnog will skip nonlinearities from the input file. This option is convenient for testing and problem search. Simple set **linear\_calculation -yes** so that the calculation should run without any trouble, and use a **control\_print** for **-post\_node\_rhside\_ratio**. The printed **-post\_node\_rhside\_ratio** should be very small, typically 1.e-10 or lower, since the calculation is linear now. If that is not the case, there may be a problem with the boundary conditions or some other problem.

A typical sequence for testing very large calculations may be following: first run with **solver -none** and check the mesh at all times; second run with **linear\_calculation\_apply -yes** to check if good linear solutions fields are obtained (check the linear results carefully); finally run your actual calculation without any special options.

The following specific actions are taken:

- Any **control\_plasti\_apply** is deleted, and **plasti\_apply** is set to **-no**.
- **mesh** is set to **-fixed\_in\_space**.
- For all **group\_\*\_memory** the memory type is set to **-total\_linear** if **materi\_displacement** is initialised, and it is set to **-updated\_linear** otherwise.
- Any **dependency\_item**, **dependency\_diagram** containing **group\_\*** data depending on one of the dof's of **dof\_label** is deleted.

- Any **group\_materi\_elasti\_hardsoil** is deleted and substituted by a **group\_materi\_elasti\_young** with *E50ref* as Young's modulus.
- Any **group\_materi\_elasti\_polynomial** is deleted and substituted by a **group\_materi\_elasti\_young** with *E0* as Young's modulus.
- Any **group\_materi\_elasti\_young\_power** is substituted by a linear **group\_materi\_elasti\_young**.
- Any **group\_materi\_plasti\_hypo\_wolffersdorff** is deleted and substituted by a **group\_materi\_elasti\_young** with *hs* as Young's modulus, and a **group\_materi\_elasti\_poisson** with value 0.2.
- Any **group\_spring\_stiffness\_nonlinear** is deleted and substituted by a **group\_spring\_stiffness** with the stiffness value at strain 0.
- Any **group\_groundflow\_nonsaturated** is deleted.
- Any **group\_interface\_gap** is deleted.
- Any **group\_interface\_materi\_hardenig** is deleted.
- Any **group\_interface\_materi\_elasti\_stiffness\_tangential\_diagram** is deleted.
- Any **group\_materi\_damage** is deleted.
- Any **group\_materi\_failure** is deleted.
- Any **group\_truss\_rope** is deleted.
- Any **contact\_\*** is deleted.
- Any **groundflow\_seepage\_\*** is deleted.

### 6.799 **materi\_damage\_apply** *switch*

If *switch* is set to **-no**, any damage data in the input file will be ignored. This is done for all timesteps.

This option is convenient for testing your input file just linear, without the need to outcomment each and every part with damage data. See also **control\_materi\_damage\_apply**.

### 6.800 **materi\_dynamic\_factor**

This option is specifically meant for dynamic calculations. When the solution is known at time *t* and is being solved in the new timestep for time *d + dt* the stresses at time *t* are used with  $1 - factor$  and the stress at time *t + dt* are used with *factor*. Thus using a factor less than 1 makes the scheme less implicit, and thus less numerical damping will occur. Default, if this option is not specified, *factor* is set to 1 (so fully implicit).

For quasi static calculations this option should not be used since it results in a loss of stability for strong nonlinearities. Also in case of dynamic calculations with heavy nonlinearity it is better to use the default timestepping method with sufficient small steps. You can try if by using this option the calculation converges; if the calculation converges it is better to use this option; if the calculation diverges by using this option it should be removed.

Using this **materi\_dynamic** option the value of **post\_node\_rhside\_ratio** is not usable anymore. So this option is typically used in combination with fixed timestepping. In fact, you should perform the dynamic calculation with typical timestep, and afterwards perform the calculation again with a smaller timestep to see if results change significantly.

In solid mechanics dynamics we always use for velocities and accelerations  $velocity^{t+dt} = (displacement^{t+dt} - displacement^t)/dt$  and  $acceleration^{t+dt} = (velocity^{t+dt} - velocity^t)/dt$ . In fluid calculations where velocities are calculated and displacements of particles are not relevant, we only have  $acceleration^{t+dt} = (velocity^{t+dt} - velocity^t)/dt$ .

### 6.801 **materi\_elasti\_young\_power\_apply** *switch*

If *switch* is set to **-no**, any nonlinearity in young dependent on a power law will be ignored; simply the constant young as encountered in the **group\_materi\_elasti\_young\_power** records will be applied at all times.

### 6.802 **materi\_failure\_apply** *switch*

If *switch* is set to **-no**, any failure data in the input file will be ignored. This is done for all timesteps.

This option is convenient for testing your input file just linear, without the need to outcomment each and every part with failure data. See also **control\_materi\_failure\_apply**.

### 6.803 **materi\_plasti\_hypo\_substepping** *index switch*

If *switch* is set to **-yes** substepping will be applied in hypoplasticity routines. If *switch* is set to **-no** substepping will not be applied in hypoplasticity routines.

If the record **control\_materi\_plasti\_hypo\_substepping** is specified that record will be used. If none record is not specified *switch* is set to **-yes**.

### 6.804 **materi\_plasti\_maximum\_iterations** *maximum\_iterations*

Plasticity needs iterations on integration point level. Default at maximum 20000 iterations are allowed. With this **materi\_plasti\_maximum\_iterations** options you can increase

the number of allowed iterations, if it looks like results are inaccurate and more iterations are needed. This might be the case in calculations with very heavy plasticity.

#### 6.805 **materi\_plasti\_tension\_apply** *switch*

If *switch* is set to **-no**, any tension-plasticity data in the input file will be ignored. This is done for all timesteps.

See also **control\_materi\_plasti\_tension\_apply**.

#### 6.806 **materi\_plasti\_visco\_apply** *switch*

If *switch* is set to **-no**, any visco-plasticity data in the input file will be ignored. This is done for all timesteps.

See also **control\_materi\_plasti\_visco\_apply**.

#### 6.807 **mesh** *specifier\_x specifier\_y specifier\_z*

If *specifier\_x* is set to **-fixed\_in\_space**, the nodal points of the mesh remain fixed in space in x-direction. If a *specifier\_x* is set to **-follow\_material**, the nodal points of the mesh will follow material displacements in x-direction. The same holds for the other directions. In 1D, you only need to give *specifier\_x*, etc.

Default each specifier is set to **-fixed\_in\_space**.

This record **mesh** only is used if **materi\_velocity** is initialised. If **materi\_displacement** is initialized each specifier is automatically set to **-fixed\_in\_space**.

#### 6.808 **mesh\_activate\_gravity\_element** *index element\_range*

See **mesh\_activate\_gravity\_time**.

#### 6.809 **mesh\_activate\_gravity\_element\_group** *index element\_group\_0 element\_group\_1 ...*

See **mesh\_activate\_gravity\_time**.

**6.810** `mesh_activate_gravity_geometry` *index geometry\_item\_name  
geometry\_item\_index*

See `mesh_activate_gravity_time`.

**6.811** `mesh_activate_gravity_method` *index method*

Set to `-method1` or `-method2`. Default Tochnog will use `-method2`.

See `mesh_activate_gravity_time`.

**6.812** `mesh_activate_gravity_stiffness_factor` *index factor*

See `mesh_activate_gravity_time`.

**6.813** `mesh_activate_gravity_time` *index time\_start time\_end*

With this record you can slowly activate gravity for elements between *time\_start* and *time\_end*.

You can specify an element range with `mesh_activate_gravity_element`. The elements you need to specify as elements range. Possible formats for the elements are a number (eg. 5), a number range (eg. `-ra 5 4 8 -ra`), or all elements ( `-all`).

Or otherwise, you can specify element group numbers with `mesh_activate_gravity_element_group`.

Or otherwise, you can specify a geometry with `mesh_activate_gravity_geometry` so that elements completely in the geometry will be used.

Tochnog will activate the elements from the bottom to the top. For each specific element the start time of activation is interpolated from the global *time\_start* and *time\_end* and the lowest coordinate of the element. Likewise, for the element end time of activation the highest coordinate is used. Typically take care that the timestep is so small that each timestep only about 10 percent of an element gets filled.

This option comes handy to slowly build dams or so, starting at the bottom and building upwards to the top.

If `mesh_activate_gravity_method` is set to `-method1`, before the element start time of activation, the element is not active in the calculation. After the element end time of activation, the element is fully active in the calculation. Between these times the element is active, but the gravity is 0 at the element start time of activation, the gravity gets its full value at the element end time of activation, and the gravity is interpolated in between. With this `-method1` the displacements for activated nodes are 0 at the moment of activation,

and grow later in time. Thus the displacements in the activation area are relative to the moment of material activation, and not relative to the moment of start of the calculation.

If **mesh\_activate\_gravity\_method** is set to **-method2**, before the element start time of activation, the element is active in the calculation, but has no gravity force yet. After the element end time of activation, the element is fully active in the calculation with full gravity force. Between these times the element is active, but the gravity is 0 at the element start time of activation, the gravity gets its full value at the element end time of activation, and the gravity is interpolated in between. With this **-method2** the displacements for activated nodes are not 0 at the moment of activation, but already have values resulting from activation of material below. For elements which are not activated yet, Tochnog will reduce the stiffness so that it will not really influence displacements inside the elements which are already being activated; the stiffness reduction factor can be specified by **mesh\_activate\_gravity\_stiffness\_factor**, and is 1.e-6 by default. For elements which are not activated yet, Tochnog will not print the elements to the gid postprocessing files; however you can demand that these elements will also be printed by specifying **-yes** in **print\_gid\_mesh\_activate\_gravity** or **control\_print\_gid\_mesh\_activate\_gravity** (default **-no**).

You can set with **mesh\_activate\_gravity\_time\_initial** when elements become active in a calculation; before the specified *time\_of\_birth* an element will not take part of the calculation.

You can only use this option not in combination with *materi\_displacement*. See also **control\_mesh\_activate\_gravity\_apply**.

#### 6.814 mesh\_activate\_gravity\_time\_initial *index time\_of\_birth*

See **mesh\_activate\_gravity\_time**.

#### 6.815 mesh\_activate\_gravity\_time\_strain\_settlement *index switch*

If *switch* is set to **-yes** then strain settlement should be used for the **mesh\_activate\_gravity\_time** record with the same index.

#### 6.816 mesh\_boundary *switch*

If *switch* is set to **-yes**, Tochnog determines the boundary of the mesh and sets **element\_boundary** and **node\_boundary** records. If *switch* is set to **-no**, Tochnog does not determine the boundary of the mesh. Default, if **mesh\_boundary** is not specified, the *switch* is **-no**.

### 6.817 `mesh_correct switch`

If *switch* is set to **-yes**, Tochnog checks that the connectivity list for quadrilateral and hexahedral interfaces is correct. If the connectivity list would not be correct (that is, according to the required sequence in Tochnog for such elements), the connectivity list will be corrected.

Default *switch* is set to **-no**.

### 6.818 `mesh_delete_geometry_moving_index geometry_moving_index`

With *geometry\_moving\_index* you tell Tochnog to excavate the mesh with the geometrical entity as specified by the **geometry\_moving\*** records with index *geometry\_moving\_index*.

### 6.819 `mesh_element_group_apply index group_0 group_1 ...`

If you specify this record, only the element groups specified will be evaluated in all timesteps. Default, if **mesh\_element\_group\_apply** is not specified, all elements groups will be used.

If **control\_mesh\_element\_group\_apply** is specified it overrules this **mesh\_element\_group\_apply** record.

### 6.820 `mesh_gid_assign_conditions_line index line_0 line_1 ...`

Assign nodes on gid lines to tochnog **geometry\_list index**. You can use geometry lists to impose geometrical conditions, see **geometry\_list**. The *index* needs to be 11, 12, ..., 20 (start with index 11, then index 12, up to maximal 20).

A simple example is:

```
mesh_gid_assign_conditions_line 11 3 4 (assign gid line 3 and 4 to geometry_list 11)
```

```
bounda_dof 10 -geometry_list 11 -velx -vely (set velocities to 0 on geometry_list 11)
```

See also **control\_mesh\_gid\_batch**.

### 6.821 `mesh_gid_assign_conditions_point index point_0 point_1 ...`

Assign nodes on gid points to tochnog **geometry\_list index**. You can use geometry lists to impose geometrical conditions, see **geometry\_list**. The *index* needs to be 1, 2, ..., 10 (start with index 1, then index 2, up to maximal 10).

See also **control\_mesh\_gid\_batch**.

**6.822 mesh\_gid\_assign\_conditions\_surface** *index surface\_0 surface\_1*  
...

Assign nodes on gid surfaces to tochnog **geometry\_list** *index*. You can use geometry lists to impose geometrical conditions, see **geometry\_list**. The *index* needs to be 21, 22, ..., 30 (start with index 21, then index 22, up to maximal 30).

See also **control\_mesh\_gid\_batch**.

**6.823 mesh\_gid\_arc\_coord** *index x\_0 y\_0 x\_1 y\_1 x\_2 y\_2*

Arc coordinates of first, second and third point. See also **control\_mesh\_gid\_batch**.

**6.824 mesh\_gid\_circle\_coord** *index x y*

Circle middle coordinates. See also **control\_mesh\_gid\_batch**.

**6.825 mesh\_gid\_circle\_element\_group** *index group*

Group number. See also **control\_mesh\_gid\_batch**.

**6.826 mesh\_gid\_circle\_hollow** *index switch*

SWitch for hollow circle.

**6.827 mesh\_gid\_circle\_radius** *index radius*

Circle radius. See also **control\_mesh\_gid\_batch**.

**6.828 mesh\_gid\_cylinder\_coord** *index x y z*

Circle base middle coordinates. See also **control\_mesh\_gid\_batch**.

**6.829** `mesh_gid_cylinder_element_group` *index group*

Group number. See also `control_mesh_gid_batch`.

**6.830** `mesh_gid_cylinder_height` *index height*

Cylinder height. See also `control_mesh_gid_batch`.

**6.831** `mesh_gid_cylinder_hollow` *index switch*

Set *switch* to **-yes** if you want the cylinder to act as a hollow zone, typically inside another zone (for example a volume zone). So this option comes handy when you want to study, for example, cylindrical excavation zones in a soil.

**6.832** `mesh_gid_cylinder_normal` *index normal\_x normal\_y normal\_z*

Cylinder normal. See also `control_mesh_gid_batch`.

**6.833** `mesh_gid_cylinder_radius` *index radius*

Cylinder radius. See also `control_mesh_gid_batch`.

**6.834** `mesh_gid_line_structured_concentrate` *index weight\_start weight\_end*

Concetrates elements for structured mesh near start or end of line. The *weight\_start* and *weight\_end* can be specified between -1 and +1. These are the mesh concentration factors for the line start and end respectively. With 0 there is no concentration. With -1 the concentration is low. With +1 the concentration is high.

Dedault, if `mesh_gid_line_structured_concentrate` is not specified, both weight factors are 0. See also `control_mesh_gid_batch`.

**6.835** `mesh_gid_line_element_group` *index group*

Group number. See also `control_mesh_gid_batch`.

**6.836** `mesh_gid_line_point` *index point\_0 point\_1*

Line points. See also `control_mesh_gid_batch`.

**6.837** `mesh_gid_line_size` *index size*

Size of elements at line. See also `control_mesh_gid_batch`.

**6.838** `mesh_gid_line_structured_nel` *index nel*

Number of elements for structured line. See also `control_mesh_gid_batch`.

**6.839** `mesh_gid_line_structured_size` *index size*

Size of elements at structured line. See also `control_mesh_gid_batch`.

**6.840** `mesh_gid_point_coord` *index x y z*

Point coordinates. In 2D you only need to specify *x* and *y*. See also `control_mesh_gid_batch`.

**6.841** `mesh_gid_rectangle_coord` *index x\_0 x\_1 y\_0 y\_1*

Rectangle coordinates of first and second point. See also `control_mesh_gid_batch`.

**6.842** `mesh_gid_rectangle_element_group` *index group*

Group number. See also `control_mesh_gid_batch`.

**6.843** `mesh_gid_rectangle_hollow` *index switch*

Set *switch* to **-yes** if you want the rectangle to act as a hollow zone, typically inside another zone (for example a surface zone). So this option comes handy when you want to study, for example, rectangular excavation zones in a soil.

**6.844** `mesh_gid_size` *element\_size*

Size of elements. See also `control_mesh_gid_batch`.

**6.845** `mesh_gid_sphere_coord` *index x y z*

Sphere middle coordinates. See also `control_mesh_gid_batch`.

**6.846** `mesh_gid_sphere_element_group` *index group*

Group number. See also `control_mesh_gid_batch`.

**6.847** `mesh_gid_sphere_hollow` *index switch*

Set *switch* to **-yes** if you want the sphere to act as a hollow zone, typically inside another zone (for example a volume zone). So this option comes handy when you want to study, for example, a hollow space in a soil.

**6.848** `mesh_gid_sphere_radius` *index radius*

Sphere radius. See also `control_mesh_gid_batch`.

**6.849** `mesh_gid_surface_element` *index element\_type*

Element type for surface. You can use one of **-tria3**, **-tria6**, **-quad4**, **-quad8**, **-quad9**, **-tet4**, **-tet10**, **-hex8**, **-hex20** and **-hex27**. If this record is not specified linear elements are generated as default, triangles in 2D and tets in 3d. See also `control_mesh_gid_batch`.

**6.850** `mesh_gid_surface_element_group` *index group*

Group number. See also `control_mesh_gid_batch`.

**6.851** `mesh_gid_surface_line` *index line\_0 line\_1 ...*

Surface lines. This option will generate 1 new surface. See also `control_mesh_gid_batch`.

**6.852** `mesh_gid_surface_structured_nel` *index nel\_0 nel\_1 ...*

Number of elements on lines of structured surface. Specify a number for each of the lines. Specify a positive number if you want to set the number of elements for the line. Specify a 0 for each of the opposing lines. See also `control_mesh_gid_batch`.

**6.853** `mesh_gid_surface_structured_size` *index size*

Size of elements on structured surface. See also `control_mesh_gid_batch`.

**6.854** `mesh_gid_volume_element_group` *index group*

Group number. See also `control_mesh_gid_batch`.

**6.855** `mesh_gid_volume_surface` *index surface\_0 surface\_1 ...*

Volume surfaces. This option will generate 1 new volume. See also `control_mesh_gid_batch`.

**6.856** `mesh_interface_triangle_coordinates` *index coord\_x\_0 coord\_y\_0  
coord\_z\_0 coord\_x\_1 coord\_y\_1 coord\_z\_1 coord\_x\_2 coord\_y\_2  
coord\_z\_2 ...*

With this option you can generate interface elements in a 3d mesh with tet4 elements. You specify the triangulated plane of the interface as sets of triangles in 3d space. For each triangle you specify for the three corner points the coordinates. For example `coord_x_0 coord_y_0 coord_z_0` are the coordinates of the first corner point, `coord_x_1 coord_y_1 coord_z_1` are the coordinates of the second corner point and `coord_x_2 coord_y_2 coord_z_2` are the coordinates of the third corner point. The combination of all triangles specifies the plane which will be intersected with the 3d tet4 mesh to generate the interface elements.

With `mesh_interface_triangle_element_group` you specify the group which will be attributed to the interface elements. With `control_mesh_interface_triangle` you specify the control index for which the generation should be done.

A typical input file looks like:

```
...
group_type 1 -materi
group_interface 1 -yes
group_interface_materi_memory 1 -total_linear
```

```

group_interface_materi_elasti_stiffness 1 1.e11 0.5e11 0.5e11
...
mesh_interface_triangle_coordinates 0. 0. 0.6 100. 0. 0.6 0. 100.
0.6
mesh_interface_triangle_element_group 1
...
control_mesh_interface_triangle 10 -yes
...

```

### 6.857 mesh\_interface\_triangle\_element\_group *index element\_group*

See `mesh_interface_triangle_coordinates`.

### 6.858 message *switch*

If *switch* is set to **-yes** the introduction message (executable name, date, conditions) will be printed. If *switch* is set to **-no** it will not be printed. Default *switch* is **-yes**.

You can also set this **message** as environment symbol to **-no** if you want to suppress messages for all calculations.

### 6.859 mpc\_apply *switch*

If *switch* is set to **-yes** then mpc conditions will be used. If *switch* is set to **-no** then mpc conditions will not be used. Default, if **mpc\_apply** is not specified, *switch* is set to **-yes**.

See also `control_mpc_apply`.

### 6.860 mpc\_element\_group *index element\_group\_0 element\_group\_1*

Each node of element of group *element\_group\_0* that is also located in an element of group *element\_group\_1* will be tied to that group by means of multi point constraints. The multi point constraints will be consistent with the shape functions at the specific isoparametric coordinates of the location of that node in the element of group *element\_group\_1*. For *element\_group\_1* you can only use isoparametric elements. As a special option you can use **-all** for *element\_group\_1*, so that all other element groups are selected.

See also `mpc_element_group_always`, `mpc_element_group_closest` and `control_mpc_element_group`.

### 6.861 mpc\_element\_group\_always index switch

If *switch* is set to **-yes** the mpc's will be generated always. If *switch* is set to **-no** the mpc's will only be generated if the considered node is not a member of the node list of the element of group *element\_group\_1* (this ensures that mpc's will only be generated if the node is completely loose from the other element). You can use the *switch* is **-no** option if you are not sure if *element\_group\_0* is connected to, or not connected to, *element\_group\_1*; with **-no** you will not get mpc's if the groups are connected; see **mpc\_\*** in the dbs file to check if mpc's are generated. So if you are not sure if surfaces are connected in gid, a typical strategy would be:

- run tochnog with **mpc\_element\_group ...** and **mpc\_element\_group\_always -no**
- if you get **mpc\_\*** records in the dbs, run again with **mpc\_element\_group ...** and **mpc\_element\_group\_always -yes**
- if you do not get **mpc\_\*** records remove **mpc\_element\_group** and **mpc\_element\_group\_always**

Default, if **mpc\_element\_group\_always** is not specified, *switch* is set to **-yes**.

### 6.862 mpc\_element\_group\_closest index switch

If *switch* is set to **-yes** the mpc's will also be generated if no element of *element\_group\_1* is found; then the closest element of *element\_group\_1* will be used.

### 6.863 mpc\_element\_group\_coord\_geometry index switch

If *switch* is set to **-yes** the mpc's will only be generated if the coordinate of the node of *element\_group\_0* is above the lowest node of *element\_group\_1*.

A typical example is when you mpc the nodes of soil with *element\_group\_0* to pile elements with *element\_group\_1*. Then only soil nodes above the toe of the pile should be mpc'd. A piece of input file will look like:

```
...
start_define
  pile_group 1
end_define
start_define
  soil_interface_group 2
end_define
...
start_define
```

```

    pile_edge geometry_line 10
end_define
pile_edge .....
...
mpc_element_group 10 soil_interface_group pile_group (mpc soil nodes to pile)
mpc_element_group_geometry 10 -pile_edge (for soil nodes located on the pile edge)
mpc_element_group_closest 10 -yes (the soil node should be mpc'd to the closest pile element)
mpc_element_group_coord_geometry 10 -yes (do this only for soil nodes above the toe of the pile)
mpc_element_group_dof 10 -velx -vely (in 2D mpc the velocities, and thus displacements)
...

```

#### 6.864 **mpc\_element\_group\_dof** *index dof\_0 dof\_1 ...*

The *dof\_0 dof\_1 ...* in **mpc\_element\_group\_dof** specify the dof's that should be set equal, e.g. **-velx**, **-vely** etc. Default, if **mpc\_element\_group\_dof** is not specified, all principal dofs will be set equal.

#### 6.865 **mpc\_element\_group\_eps\_iso** *index eps*

With *eps* you can specify the tolerance on the isoparametric coordinates for the element of *element\_group\_1* below which a node of *element\_group\_0* is considered to be located in *element\_group\_1*. Default, if **mpc\_element\_group\_eps\_iso** is not specified, *eps* is set to **1.e-4**.

#### 6.866 **mpc\_element\_group\_geometry** *index geometry\_entity\_item geometry\_entity\_index*

Select a geometry for nodes of *element\_group\_0*.

#### 6.867 **mpc\_element\_group\_keep** *index switch*

If *switch* is set to **-yes** the generated mpc's will kept in the remainder of the calculation. As a typical application you can use this option to save computing time if you know that the mpc's need not to be changed during time steps. Or as another example you can use this option if you want that the mpc remains active even if the element for which the mpc is generated gets outside the specified geometry of **mpc\_element\_group\_geometry**.

### 6.868 **mpc\_geometry\_index** *geometry\_entity\_item\_0 geometry\_entity\_index\_0 geometry\_entity\_item\_1 geometry\_entity\_index\_1*

See also **mpc\_geometry\_method**.

If *method* in **mpc\_geometry\_method** is set to **-method0** the following mpc's will be generated. This record automatically generates **mpc\_node\_number** and **mpc\_node\_factor** records such that dof's in the second geometry *geometry\_entity\_item\_1 geometry\_entity\_index\_1* become equal to the dof's in the first geometry *geometry\_entity\_item\_0 geometry\_entity\_index\_0*. The *switch\_x switch\_y switch\_z* in **mpc\_geometry\_switch** specify the coordinates that should be checked to judge if a node in the second geometry is considered to have the same position as a node in the first geometry, and thus should get the same dof's. Only the coordinate for which the corresponding switch is set to **-yes** will be checked. For example in 3D if **-yes -no -no** are used then a node in the second geometry gets the same dof's of a node in the first geometry in it has (almost) equal x-coordinate; the y and z-coordinate are irrelevant. In 2D only *switch\_x switch\_y* need to be specified. With **mpc\_geometry\_tolerance** you can set the tolerance beneath which nodes of the first geometry and second geometry are assumed to have the same coordinate. If **mpc\_geometry\_tolerance** is not specified then a tolerance of 1.e-4 is used.

If *method* in **mpc\_geometry\_method** is set to **-method1** the following mpc's will be generated. You should only specify the first geometry. The dof's of the nodes in this first geometry become equal. The first node of this first geometry becomes the master, all other nodes in this first geometry become slave. If you want to know which node is the first node in this first geometry, use a **control\_print ... -node** with a **print\_filter** for the first geometry.

If *method* in **mpc\_geometry\_method** is set to **-method2** the following mpc's will be generated. You should only specify the first geometry. Unknowns of the nodes with equal coordinate in this first geometry become equal.

### 6.869 **mpc\_geometry\_method** *index method*

See **mpc\_geometry**. If this **mpc\_geometry\_method** is not specified then *method* will be set to **-method0**.

### 6.870 **mpc\_geometry\_switch** *index switch\_x switch\_y switch\_z*

See **mpc\_geometry**.

### 6.871 **mpc\_geometry\_tolerance** *index tolerance*

See **mpc\_geometry**.

### 6.872 **mpc\_geometry\_dof** *index dof\_0 dof\_1 ...*

The *dof\_0 dof\_1 ...* in **mpc\_geometry\_dof** specify the dof's that should be set equal, e.g. **-velx**, **-vely** etc.

### 6.873 **mpc\_linear\_quadratic** *switch*

If *switch* is set to **-yes** this option is activated.

If you have a mesh with both linear elements and quadratic elements, the mesh is not compatible at the places where the linear elements and quadratic elements meet at a common interface. There some of the quadratic element nodes are not attached to the linear elements, and so non-compatible solution fields occur.

This **mpc\_linear\_quadratic** option allows you to automatically prevent the non-compatible solution fields. Tochnog imposes a multi point constraint on all non-compatible solution fields between the linear and quadratic elements, so that the extra nodes of the quadratic elements are forced to follow the solution field of the linear elements, and so compatibility is ensured again.

This option typically can be used to model structural parts like beams, sheet piles, tunnel shells etc with quadratic elements, and the surrounding soil with linear element. Use one quadratic element in the structural part thickness direction, and extra one quadratic soil element attached to the structural element. For the remaining soil elements use linear elements. In this way, the stiff structural elements can deform flexible enough, and you save computer time by modeling most of the soils with linear elements.

### 6.874 **mpc\_node\_factor** *index factor\_10 factor\_11 ... factor\_20 factor\_21 ...*

See **mpc\_node\_number**.

### 6.875 **mpc\_node\_number** *index node\_0 dof\_0 node\_1 dof\_10 dof\_11 ... node\_2 dof\_20 dof\_21 ...*

This Multi Point Constraint record **mpc\_node\_number** allows you to set constraints between dof's at different nodes. The *dof\_0* specifies the dof at node number *node\_0* which will be constrained. It will be constrained to dof's *dof\_10*, *dof\_11*, ... of *node\_1* and *dof\_20*, *dof\_21*, ... of *node\_2*, etc. Only principal dof's can be specified. Principal dof's are material velocities, groundwater pressure, temperature in the convection diffusion equation, etc.; see the start of the data section for a definition of principal dof's. With

**mpc\_node\_factor** you can set multiplication factors for the constraints. If you don't specify **mpc\_node\_factor** a 1 is used for all factors.

Example:

```
...
mpc_node_number 10 1 -velx 2 -velx 3 -vely
mpc_node_factor 10 7. 9.
```

In this example the  $velx\_1 = 7. * velx\_2 + 9. * vely\_3$  where  $velx\_1$  is the x-velocity at node 1 etc. Node number *node\_0* is this slave node which depends on nodes *node\_1* etc. which are the master nodes.

Boundary conditions with **bounda\_dof** and **bounda\_time** cannot be specified for slave nodes.

See also **mpc\_geometry** for easy generation of multi point constraints.

#### 6.876 **node** *index coord\_0 coord\_1 coord\_2*

Coordinates of node *index*. In 1D, only *coord\_0* should be specified, etc..

You are not allowed to put free nodes (not attached to any element) in your model. These free nodes will be removed automatically.

#### 6.877 **node\_boundary** *index switch*

The *switch* will be set to **-yes** if the node with index *index* is located on the boundary of the mesh.

This record will only become available if **mesh\_boundary** is set to **-yes**. This record is meant for printing only, it should not be set by the user.

#### 6.878 **node\_bounded** *index indicator\_dof\_0 indicator\_dof\_1 ...*

This record is for printing only, it is not an input record. This record indicates if dof's in the node are bounded via a **bounda\_dof** record; then the corresponding indicator is set to 1, else it remains 0.

**6.879 node\_bounded\_index** *index bounda\_dof\_index\_0 bounda\_dof\_index\_1*  
 ...

This record is for printing only, it is not an input record. This record list the index of the **bounda\_dof** record by which the dof's are bounded. This index is only filled if the dof 's really bounded, so if the corresponding value in the **node\_bounded** record is set to 1.

**6.880 node\_convection\_apply** *index switch*

If *switch* is set to **-no** convection contributions in node *index* are de-activated in case they are activated for the whole mesh by **convection\_apply** or **control\_convection\_apply**.

**6.881 node\_damping** *index damping\_x damping\_y damping\_z*

This record adds a discrete damper to node *index* in *x*, *y* and *z* direction respectively. In 1D only *damping\_x* needs to be specified, etc. The damper will lead to a nodal force of the size *damping\_x* \* *v\_x* where *v\_x* is the velocity in *x* direction. The same holds for the *y* and *z* direction.

**6.882 node\_deformed\_mesh** *index coord\_0 coord\_1 coord\_2*

After the calculation, this record will contain deformed coordinates of node *index*.

If **materi\_displacement** is initialised these are the initial start coordinates **node\_start\_refined** plus the displacements.

If **materi\_velocity\_integrated** is initialised and the node follows the material with **-follow\_material** these are the current coordinates of the node **node**.

If **materi\_velocity\_integrated** is initialised and the node is fixed in space with **-fixed\_in\_space** these are the initial start coordinates **node\_start\_refined** plus the integrated velocities.

Else these are equal to the current node **node**.

In 1D, only *coord\_0* is filled, etc..

**6.883 node\_dof** *index dof\_0 dof\_1 ...*

*dof\_0 dof\_1 ...* are the degrees of freedom (dof's) at the node with number *index*. The total number and type of the dof's depends on the initialization part. Each node has the same dof's.

Unknowns like pressure, temperature, etc. are primary dof's. The other dof's, space derivatives and the time derivative, are not primary dof's. In the example below, **-temp** is 1., **-xtemp** is 0.2 and **-ttemp** is 0.1 in node 6

```
...
number_of_space_dimensions 1
derivatives
condif_temperature
end_initia
...
node_dof 6 1.0 0.2 0.1
...
```

Default all values in the **node\_dof** records are set zero at the start of the calculation.

These **node\_dof** records contain principal dof's for all elements (displacements, temperatures, etc). Other dof's like strains, stresses etc. are only filled for the normal isoparametric elements; thus, for example, strain and stress results for interfaces elements are not placed in the **node\_dof** records.

See also: **dof\_label** and **post\_point**.

#### 6.884 **node\_dof\_calcul** *index ...*

See **post\_calcul**.

#### 6.885 **node\_dof\_start\_refined** *index dof\_0 dof\_1 ...*

This record will be filled with *dof\_0 dof\_1 ...*, which are the degrees of freedom (dof's) as specified at the start of the calculation. at the node with number *index*.

If the mesh has been refined, these start values hold for the refined mesh.

See also **node\_dof** and **node\_start\_refined**.

#### 6.886 **node\_dynamic\_pressure** *index value*

With this record you can specify for node *index* the dynamic pressure. Thus, the dynamic pressure as normally calculated will be overruled with this *value*.

**6.887 node\_force** *index force\_x force\_y force\_z*

With this record you can input a discrete nodal force at node *index*. In 1D you only should specify the force in x-direction. In 2D you only should specify the force in x- and y-direction.

**6.888 node\_geometry\_present** *index geometry\_item\_name\_0 geometry\_item\_index\_0 geometry\_item\_name\_1 geometry\_item\_index\_1*  
...

This record lists for node *index* the geometries in which it is present. So it is a print record only, for checking if the geometries include exactly the nodes that you want. You can switch on or off filling of these records by setting **print\_node\_geometry\_present** to **-yes** or **-no**.

**6.889 node\_inertia** *index inertia\_dof\_0 inertia\_dof\_1* ...

This record will be filled with calculated inertia terms degrees of freedom (dof's) as specified at the start of the calculation. at the node with number *index*. For material velocity that is the mass inertia term in the node.

**6.890 node\_mass** *index mass\_x mass\_y mass\_z*

This record adds a discrete mass to node *index* in *x*, *y* and *z* direction. In 1D only the *x*-mass needs to be specified, etc. The mass will lead to a nodal force of the size  $mass_x * \dot{v}_x$  where  $\dot{v}_x$  is the acceleration, and to a gravity force if **force\_gravity** is specified. The same holds for the *y* and *z* direction.

**6.891 node\_mesh** *index* ...

Same as **mesh**, but now specified per node however. The *index* specifies the node number. If this **node\_mesh** record is specified for a node, it overrules the **mesh** record.

**6.892 node\_rhside** *index rhside\_0 rhside\_1* ...

This record will contain after the calculations the unbalance forces.

For the temperature equation, this will give the heat flow normal to the outer surface (the heat flux to the environment) at prescribed temperatures. For velocity dof's, this will give the force vector at prescribed displacements. For the pressure in the ground flow equation,

this will give the ground flow to the environment at prescribed pressures. For non-prescribed dofs the record will contain the numerical unbalance, and should be close to zero.

The *index* is the node number.

#### 6.893 **node\_\_slide** *index slide\_number*

With **node\_\_slide** you can specify of a specific node *index* if it belongs to a sliding geometry with index *slide\_number*. For the sliding geometry **slide\_\_geometry** is not needed anymore because the **node\_\_slide** already specifies which nodes belong to the sliding geometry.

#### 6.894 **node\_\_static\_\_pressure** *index value*

With this record you can specify for node *index* the static pressure. Thus, the static pressure as normally calculated will be overruled with this *value*.

#### 6.895 **node\_\_start\_\_refined** *index coord\_0 coord\_1 coord\_2*

After the calculation, this record will contain coordinates of node *index* as specified at the start of the calculation. If the mesh has been refined this record will contain the start coordinates for the refined mesh. In 1D, only *coord\_0* is filled, etc..

#### 6.896 **node\_\_stiffness** *index stiffness\_x stiffness\_y stiffness\_z*

This record adds a discrete stiffness to node *index* in *x*, *y* and *z* direction respectively. In 1D only *stiffness\_x* needs to be specified, etc. The stiffness will lead to a nodal force of the size *stiffness\_x \* u\_x* where *u\_x* is the displacement in *x* direction. The same holds for the *y* and *z* direction. Condition: also **materi\_\_velocity\_\_integrated** or **materi\_\_displacement** should be initialized.

#### 6.897 **node\_\_support\_\_edge\_\_normal\_\_plasti\_\_tension\_\_status** *index status*

This record will contain after a calculation the status of a node for the **support\_\_edge\_\_normal\_\_plasti\_\_tension** or **support\_\_edge\_\_normal\_\_plasti\_\_tension\_\_double** option. If the node is opened due to tension plasticity the status is set to **-opened**. If the node is closed the status is set to **-closed**.

### 6.898 **node\_total\_pressure** *index value*

With this record you can specify for node *index* the total pressure. Thus, the total pressure as normally calculated will be overruled with this *value*.

### 6.899 **nonlocal** *nonlocal\_radius*

By specifying this record in combination with a viscoplastic model, like **group\_materi\_plasti\_visco\_power**, a nonlocal yield rule *fn* will be used in the viscoplastic law. The nonlocal yield rule needs to be initialized as dof by the **materi\_plasti\_f\_nonlocal** record in the initialization part. The nonlocal yield rule *fn* in a point is determined by an averaging of the local yield rule *f* in neighboring points and using gauss weighting functions for this (i.e. the larger the distance the less the neighboring point contributes to the nonlocal yield rule). The averaging is done over a region with radius *nonlocal\_radius*.

In this way, you can prevent unlimited localization and so mesh dependency, in calculations with softening plasticity.

See also **nonlocal\_name**.

### 6.900 **nonlocal\_name** *name*

With *name* you specify the name of the plasticity model that should be treated nonlocal, eg **-group\_materi\_plasti\_mohr\_coul**. You can only specify one name, so only one plasticity model can be used as nonlocal model.

### 6.901 **plasti\_apply** *switch*

If *switch* is set to **-no**, any plasticity data in the input file will be ignored. This is done for all timesteps.

This option is convenient for testing your input file just linear, without the need to outcomment each and every part with plasticity data. See also **control\_plasti\_apply**.

### 6.902 **post\_apply** *index switch*

Setting *switch* to **-no** prevents post processing commands to be evaluated. Postprocessing commands have **post** in the name (only the **post\_node\_rhside\_ratio** will be evaluated always, independent of **post\_apply**).

Default, if **post\_apply** is not specified, the switch is set to **-yes**.

### 6.903 post\_calcul dof\_0 operat\_0 dof\_1 operate\_1 ...

This records activates calculation post results. The *dof\_0 dof\_1* etc. refers to a *dof*, and possibilities for *dof* are listed below. The *operat\_0 operat\_1* etc. refers to an *operat*, and possibilities for *operat* are listed below.

Here *dof* can be one of the matrices

-**materi\_stress**,  
-**materi\_strain\_elasti**,  
-**materi\_strain\_plasti**,  
-**materi\_strain\_plasti\_compression**,  
-**materi\_strain\_plasti\_diprisco**,  
-**materi\_strain\_plasti\_druckprag**,  
-**materi\_strain\_plasti\_hardsoil**,  
-**materi\_strain\_plasti\_tension**,  
-**materi\_strain\_plasti\_vonmises**,  
-**materi\_strain\_total** or *dof* can be one of the vectors -**materi\_velocity**, -**materi\_displacement**,  
or *dof* can be one of the scalars -**condif\_temperature**, -**groundflow\_pressure**.

The results of these calculations are stored for each **node\_dof** record in a **node\_dof\_calcul** record, and are stored for each **post\_point\_dof** record in a **post\_point\_dof\_calcul** record, and are stored for each **post\_line\_dof** record in a **post\_line\_dof\_calcul** record, and are stored for each **post\_quadrilateral\_dof** record in a **post\_quadrilateral\_dof\_calcul** record.

We denote a matrix *dof* with  $A_{ij}$  and denote a vector *dof* with  $A_i$ , and denote a scalar *dof* with  $a$ . If *operat* is -**absol** then the absolute value of a scalar  $a$  is calculated.

If *operat* is -**average** then  $\frac{1}{3}(A_{11} + A_{22} + A_{33})$  is calculated for a matrix or  $\frac{1}{3}(A_1 + A_2 + A_3)$  is calculated for a vector.

If *operat* is -**negative** then the average of the negative principal values for a matrix is calculated. If **materi\_strain\_plasti** is taken for the matrix  $A_{ij}$ , then this operator typically can be used as a measure for the amount of compression failure (crunching).

If *operat* is -**positive** then the average of the positive principal values for a matrix is calculated. If **materi\_strain\_plasti** is taken for the matrix  $A_{ij}$ , then this operator typically can be used as a measure for the amount of tensile failure (cracking).

If *operat* is -**prival** then three principal values of a matrix  $A_{ij}$  are calculated. Each principal value contains the size of the principal vector. The principal values are ordered (the first value is the smallest one, and the last value is the largest one).

If *operat* is -**privec** then three principal vectors of a matrix  $A_{ij}$  are calculated. Each principal vector contains the  $x$ ,  $y$  and  $z$  component of the principal vector. The same ordering as used for -**prival** is used here also.

If *operat* is -**size\_tot** then  $\sqrt{A_{ij}A_{ij}}$  is calculated for a matrix or  $\sqrt{A_iA_i}$  is calculated for a vector. This measures the size of a matrix or the size of a vector.

If *operat* is **-size\_dev** then  $\sqrt{B_{ij}B_{ij}}$  is calculated where  $B_{ij}$  is the deviatoric part of a matrix  $A_{ij}$ :  $B_{ij} = A_{ij} - \delta_{ij} \frac{A_{11}+A_{22}+A_{33}}{3}$  where  $\delta_{ij}$  is 1 if  $i = j$  and is 0 otherwise. This measures the size of the deviatoric part of the matrix.

Specially for **-quad4**, **-quad9**, **-hex8** and **-hex27** elements you can set *operat* to **-force** in case *dof* is **-materi\_stress**. Then forces and moments are calculated in these isoparametric elements. See also **post\_calcul\_materi\_stress\_force\_element\_group**.

Specially for geotechnics you can set *operat* to **-total\_pressure** in case *dof* is **-materi\_stress**. Then the total stress is calculated from the effective stress and the groundflow total pressure. This option is not valid in combination with undrained pressures as obtained by **group\_materi\_undrained\_capacity**.

Specially for geotechnics you can set *operat* to **-static\_pressure** in case *dof* is **-groundflow\_pressure**. Then the static pressure is calculated.

Specially for geotechnics you can set *operat* to **-dynamic\_pressure** in case *dof* is **-groundflow\_pressure**. Then the dynamic pressure is calculated.

Specially for geotechnics you can set *operat* to **-k0** in case *dof* is **-materi\_stress**. Then the ratio of horizontal and vertical stresses is calculated. If 2D this is the ratio  $0.5 \frac{\sigma_{xx} + \sigma_{zz}}{\sigma_{yy}}$ . If 3D this is the ratio  $0.5 \frac{\sigma_{xx} + \sigma_{yy}}{\sigma_{zz}}$ .

Specially for geotechnics you can set *operat* to **-young\_apparent** in case *dof* is **-materi\_stress**. Then the apparant Young modulus is calculated from the incremental strains and incremental stresses. If determination is not possible (for almost zero incremental strains) the apparent young is put to 0. See also **post\_calcul\_apparent\_total**.

Specially for geotechnics you can set *operat* to **-poisson\_apparent** in case *dof* is **-materi\_stress**. Then the apparent Poisson ratio is calculated from the incremental strains and incremental stresses. If determination is not possible (for almost zero incremental strains) the apparent poisson is put to 0. See also **post\_calcul\_apparent\_total**.

Specially for geotechnics you can set *operat* to **-total\_pressure** in case *dof* is **-groundflow\_pressure**. Then the total pressure is calculated.

Specially for geotechnics you can set *operat* to **-safety\_lifting** in case *dof* is **-materi\_stress**. Then the hydraulic safety factor  $\frac{\sigma_{\text{vertical}} + p_{\text{total}}}{p_{\text{total}}}$  is calculated. In 1D  $\sigma_{\text{vertical}} = \sigma_{xx}$ , in 2D  $\sigma_{\text{vertical}} = \sigma_{yy}$  and in 3D  $\sigma_{\text{vertical}} = \sigma_{zz}$ ; see also **post\_calcul\_safety\_method**.

Specially for geotechnics you can set *operat* to **-safety\_piping** in case *dof* is **-materi\_stress**. Then the hydraulic safety factor  $\frac{\sigma_{\text{vertical}} + p_{\text{dynamic}}}{p_{\text{dynamic}}}$  is calculated; see also **post\_calcul\_safety\_method**.

The next piece of input file

```
...
materi_stress
```

```

materi_strain_plasti
end_initia
...
post_calcul-materi_stress-size_dev-materi_strain_plasti-size_tot
...
control_timestep 1 ...
control_print 1 -node_dof_calcul

```

will print records like

```
node_dof_calcul index 0.2 1.1e-4
```

Here the 0.2 is the equivalent Von Mises stress and  $1.1e-4$  measures the plastic strain matrix.

See also **post\_calcul\_absolute** and **post\_calcul\_label**.

#### 6.904 **post\_calcul\_absolute** *switch*

If *switch* is set to **-yes** all results of **post\_calcul** are set to be positive values. This may be done if you prefer positive values in your presentation of results.

#### 6.905 **post\_calcul\_apparent\_total** *switch*

If *switch* is set to **-yes**, the total strains and total stresses (as opposed to incremental) will be used to calculate the apparent young modulus and poisson ratio. If *switch* is set to **-no**, the incremental strains and incremental stresses will be used. Default, if **post\_calcul\_apparent\_total** is not specified, the *switch* is set to **-no**.

#### 6.906 **post\_calcul\_label** *doflabel\_0 label\_1 ...*

This record will be filled with the names of the data that is calculated by means of the **post\_calcul** option. The first name comes from the first *dofoperat* in **post\_calcul**, the second name comes from the second *dofoperat* in **post\_calcul**, etc. You can find this record in the dbs file after a calculation.

#### 6.907 **post\_calcul\_limit** *lower\_0 upper\_0 lower\_1 upper\_1 ...*

With this record you can specify the lower and upper allowed values for all calculated results. With *lower\_dof\_0* you specify the lower allowed value for the first result. With

*upper\_dof\_0* you specify the upper allowed value for the first result. Etc.

#### 6.908 **post\_calcul\_materi\_stress\_force\_average** *switch*

See first **post\_calcul\_materi\_stress\_force\_element\_group**.

This **post\_calcul\_materi\_stress\_force\_average** option is only available for **quad9** and **hex27** elements. It can be used if forces and moments are primarily calculated in two opposing end faces of the **quad9** and **hex27** element. If *switch* set to **-yes**, the forces and moments of nodes in the plane between the two end faces will be set to the averaged values from the forces and moments on the two opposing end faces. If *switch* set to **-no** this is not done. Default *switch* is **-yes**.

#### 6.909 **post\_calcul\_materi\_stress\_force\_direction\_exclude** *dir\_x dir\_y dir\_z*

See first **post\_calcul\_materi\_stress\_force\_element\_group**.

In 3D, Tochnog needs to know for which element sides it should determine forces and moments. For this purpose you need to specify this direction *dir\_x dir\_y dir\_z*. All element sides with normals in this direction will be neglected; no forces and moments will be determined for such sides.

Typically, in a tunnel calculation you take the tunnel length direction as *dir\_x dir\_y dir\_z*.

#### 6.910 **post\_calcul\_materi\_stress\_force\_direction\_exclude\_epsilon** *eps*

With *eps* you can influence which normals are considered to be in the specified exclude direction. A small *eps* specifies that only very precise normals in the specified direction will be excluded. A large *eps* specifies that also not precise normals in the specified direction will be excluded. In fact *eps* is the difference from inproduct between the specified exclude direction with the normal direction and 1. Default *eps* is  $1.e - 8$ .

#### 6.911 **post\_calcul\_materi\_stress\_force\_direction\_include** *dir\_x dir\_y dir\_z*

See first **post\_calcul\_materi\_stress\_force\_element\_group**.

In 3D, Tochnog needs to know for which element sides it should determine forces and moments. For this purpose you need to specify this direction *dir\_x dir\_y dir\_z*. All

element sides with normals perpendicular to this direction will be neglected; no forces and moments will be determined for such sides.

Typically, in a sheet pile calculation you take the sheet pile height direction as *dir\_x dir\_y dir\_z*.

### 6.912 **post\_calcul\_materi\_stress\_force\_direction\_include\_epsilon** *eps*

With *eps* you can influence which normals are considered to be perpendicular to the specified include direction. A small *eps* specifies that only normals precisely perpendicular to the specified direction will be excluded. A large *eps* specifies that also normals not precisely perpendicular to the specified direction will be excluded. In fact *eps* is the difference from inproduct between the specified include direction with the normal direction and 0. Default *eps* is  $1.e - 8$ .

### 6.913 **post\_calcul\_materi\_stress\_force\_element\_group** *element\_group\_0* *element\_group\_1 ...*

With the **post\_calcul -mater\_i\_stress -force** option the normal force, shear force and moment(s) are calculated for the isoparametric elements **-quad4**, **-quad9**, **-hex8** and **-hex27**. This option is meant for structures like sheet piles, tunnel shells, etc. where there is only 1 element over the thickness of the structure. Thus the element has a thickness equal to the complete thickness of the structure, and the length of the element is a part of the total length of the structure (e.g. tunnel length).

In the following definitions of forces and moments, *n* denotes the normal to an element side, *t* denotes the thickness direction in the side, and *l* denotes the length direction. The 2D and 3D normal force **nor** results is defined by the normal stresses  $\sigma_{nn}$  integrated over the thickness. The 2D and 3D shear force **she** results is defined by the shear stresses  $\sigma_{nt}$  integrated over the thickness. The 2D moment **mom** and 3D moment **mom1** are defined by the moment contributions of normal stresses  $\sigma_{nn}$  with a distance in thickness direction  $d_t$  relative to the middle of the element, integrated over thickness direction (radial bending moment in tunnel shell, thickness bending moment in sheet pile, etc.). The 3D moment **mom2** is defined by the moment contributions of normal stresses  $\sigma_{nn}$  with a distance in length direction  $d_l$  relative to the middle of the element, integrated over thickness direction (bending moment in tunnels, sheet piles, etc.).

The forces and moments will be calculated per unit length *l* of the isoparametric element, where *l* is the size of the element in length direction. In a 3D calculation, the length of an element is determined from the nodal coordinates differences in length direction. In a axi-symmetric 2D calculation, the length of the elements is set to  $2 * \text{PI} * \text{radius}$  by Tochnog (notice that with this definition values cannot be calculated at the symmetry axis with zero

radius). In a plane 2D calculation, the length of the elements is set to 1 by Tochnog.

The normal force and moment(s) are given the proper sign (plus or minus). For example, a positive normal force means that the structure is under tension. For the shear force, however, always a positive value is calculated by Tochnog, so only the size of the shear force is available (and not the direction of the shear force).

For all of the forces and moment vectors, we want to display the vector in thickness direction of the structure, to get a clear view in postprocessors (e.g. GID). Thus, the components in global x- and y-direction are determined such that the vector direction is in thickness direction of the structure. Because of this, the components by themselves are not the real physical components of the force or moment; they are only convenient values for getting clear plots in postprocessors. However, the size of the vector formed by these components (square root of components squared), indeed is the real physical size of the force or moment, so the size can indeed be used for design purposes. For your convenience, the size of each vector is also calculated automatically by Tochnog. For example, for the normal forces Tochnog calculates **-norx\_sig**, **-nory\_sig** and **-nors\_sig** which are the global plot vector x-component, y-component and the physical real size respectively.

To enable a correct force or moment direction in either the positive or negative thickness direction, Tochnog wants you to specify **post\_calcul\_materi\_stress\_force\_reference\_point**.

In 3D, you need to specify either **post\_calcul\_materi\_stress\_force\_direction\_exclude** or **post\_calcul\_materi\_stress\_force\_direction\_include**. With these records you can determine for which element sides forces and moments should be determined. The direction and element should be such that for each element for which you want to determine forces and moments exactly 4 sides should be consistent with the specified direction. Otherwise the present option for determination of forces and moments is not available for the element. Only one of **post\_calcul\_materi\_stress\_force\_direction\_exclude** and **post\_calcul\_materi\_stress\_force\_direction\_include** should be specified, not both.

The *element\_group\_0 element\_group\_1 ...* of this **post\_calcul\_materi\_stress\_force\_element\_group** specify the groups of isoparametric elements for which the forces and moments should be determined by Tochnog.

Summary of conditions for the **post\_calcul\_materi\_stress\_force** option to work well:

- Only 1 element in thickness direction.
- Elements in 3D should be regular shaped in length direction. That is, the element sides perpendicular to the length direction should be completely parallel.
- At least 1 timestep should be done (since element forces needed for this option are setup in a timestep)

**6.914** `post_calcul_materi_stress_force_reference_point` *x\_0 y\_0 z\_0 x\_1 y\_1 z\_1 ...*

See first `post_calcul_materi_stress_force_element_group`.

For example tunnels typically are of circular or piecewise circular geometry. To get a correct direction of the calculated forces and moments, Tochnog needs to know the approximate middle point of the tunnel, so that it can put all negative forces and moments and positive forces and moments consistently outwards or inwards in thickness direction of the structure. Thus, you need to specify with this `post_calcul_materi_stress_force_reference_point` record the approximate middle point of the tunnel that you are evaluating for each of the element groups. In case you have a sheet pile, you should specify a reference point on a large perpendicular distance away from the sheet pile.

You need to specify a reference point for each element group specified in `post_calcul_materi_stress_force_element_group`.

In 3D you need to specify the x, y and z value for each reference point. In 2D you only need to specify the x and y value for each reference point.

See also `post_calcul_materi_stress_force_plot_switch`.

**6.915** `post_calcul_materi_stress_force_outer` *switch*

If *switch* is set to **-yes**, the forces and moments are only calculated for the nodes at the outer sides of the elements; these are the nodes which have the furthest distance relative to the reference point. This will give a bit more nice vector plots.

Default, if `post_calcul_materi_stress_force_outer` is not specified, *switch* is set to **-no**. This will give a bit more nice contour fill plots.

**6.916** `post_calcul_materi_stress_force_plot_switch` *switch\_0 switch\_1 ...*

If you don't like the direction in which tochnog draws the vectors (outward or inward), you can switch the direction by setting the corresponding switch to **-yes**. In 2D you need to specify a switch for the normal force, shear force and moment. In 3D you need to specify a switch for the normal force, shear force and two moments.

**6.917** `post_calcul_materi_stress_force_thickness_switch` *switch\_element\_group\_0 switch\_element\_group\_1 ...*

See first `post_calcul_materi_stress_force_element_group`.

In 3D Tochnog normally assumes that the shortest element direction in the side where forces

and moments are calculated is the structure thickness direction. If that is not the case, e.g. if you have very short elements in a tunnel length direction, then you need to explain Tochnog that it should switch to the longest element direction as structural thickness direction, by setting a to **-yes**.

This ensures that the shear force is always really calculated over the structural thickness, and the first moment is really the moment over the structural thickness.

If you specify **post\_calcul\_materi\_stress\_force\_thickness\_switch** you need to give a switch for each element group of **post\_calcul\_materi\_stress\_force\_element\_group**.

#### **6.918 post\_calcul\_multiply** *factor\_0 factor\_1 ...*

With this record you can specify a multiplication factor for each calculated item. This comes handy when you prefer another definition. If you specify **post\_calcul\_multiply**, you need to give a factor for each item.

#### **6.919 post\_calcul\_safety\_default** *eps value*

Specifically for safety lifting and piping calculations division by pressure values equal to zero can occur. With this **post\_calcul\_safety\_default** record you can prevent such division. If the absolute of the pressure value for the division is smaller than the specified *eps*, the safety factor will be set to the user specified *value*.

In case this record is not specified we set *eps* to something very small, and *value* to 0.

#### **6.920 post\_calcul\_safety\_maximum** *value*

Specifically for safety lifting and piping calculations you can limit the calculated safety factor to this specified maximum *value*. This comes convenient if you get excessive large values in a calculation due to numerical accuracy in the calculation.

In case this record is not specified we set *value* to something very large.

#### **6.921 post\_calcul\_safety\_method** *method*

You can determine with this option how the hydraulic piping and lifting safety should be determined. If you set *method* to **-vertical** the safety factors will be determined using the vertical stress (zz-stress in 3D, yy-stress in 2D, xx-stress in 1D); this is the default, as described in the **post\_calcul** command. Thus you get one value for the safety piping and one value for the safety lifting.

If you set *method* to **-prival** the safety factors will be determined using the three principal stresses (principal stress 0, principal stress 1, principal stress 2). Thus you get three values for the safety piping and three values for the safety lifting.

If you set *method* to **-global** the safety factors will be determined using the three global normal stresses (xx-stress, yy-stress, zz-stress). Thus you get three values for the safety piping and three values for the safety lifting.

Setting *method* to **-vertical** is the classical definition used in most text books. However since the critical direction in complex calculations will not always be in the vertical direction, it is also of interest to study the hydraulic safety factors with the principal stress values (**-prival**). And for some situation, like soil near a retaining wall, it may be of interest to study the hydraulic safety factors with global normal stresses (**-global**).

In the dbs file after a calculation you can see in the **post\_calcul\_label** record the naming of the calculated hydraulic safety factors.

## 6.922 post\_calcul\_static\_pressure static\_pressure

With this option you can directly specify the static pressure to be used in postprocessing by **post\_calcul-groundflow\_pressure-static\_pressure** for the complete domain.

See also **post\_calcul\_static\_pressure\_height** if you want to specify a static pressure height instead.

## 6.923 post\_calcul\_static\_pressure\_height coord\_min,0 coord\_max,0 height\_ref,0 coord\_min,1 coord\_max,1 height\_ref,1 ...

Using this option the static pressure as required by **post\_calcul-groundflow\_pressure-static\_pressure** is determined relative to the reference height, and not anymore to a groundwater level. Thus, the  $\Delta z$  in the equation for  $p_{\text{static}} = \rho g \Delta z$  is taken relative to the specified reference height in this **post\_calcul\_static\_pressure\_height** record.

You can specify multiple regions. The first region is between vertical coordinate *coord\_min,0* and *coord\_max,0*. The *coord\_min,0* and *coord\_max,0* themselves are included as part the region. If a node is inside this region the *height\_ref,0* is used as phreatic level height in the equation for the static pressure. The second region is between vertical coordinate *coord\_min,1* and *coord\_max,1*. The *coord\_min,1* and *coord\_max,1* themselves are included as part the region. If a node is inside this region the *height\_ref,1* is used as phreatic level height in the equation for the static pressure.

If a node is not inside any of the regions, and if the groundflow phreatic level itself is not specified, the static pressure cannot be determined and remains zero.

See also **post\_calcul\_static\_pressure\_height\_element\_group**.

**6.924** **post\_calcul\_static\_pressure\_height\_element\_group** *element\_group\_0*  
*element\_group\_1* ...

Restrict the regions of **post\_calcul\_static\_pressure\_height** to specific element groups. The region between *coord\_min,0* and *coord\_max,0* is valid for element group *element\_group\_0*. The region between *coord\_min,1* and *coord\_max,1* is valid for element group *element\_group\_1*. Etc.

You need to specify an element group for each and every region. As a special option you can specify **-all** for an element group number; then the corresponding region is valid for all element groups.

**6.925** **post\_count** *dataitem\_name\_0 dataitem\_name\_1* ...

With this **post\_count** record you can specify data items for which the number of active indices should be counted. The results will be placed in the record **post\_count\_result**.

For example count the number of active elements, nodes and geometry points by:

```
...  
post_count -element -node -geometry_point ...
```

**6.926** **post\_data** *index dataitem\_name\_0 dataitem\_index\_0 dataitem\_number\_0*  
*dataitem\_name\_1 dataitem\_index\_1 dataitem\_number\_1* ...

The specified data items are taken, and each is multiplied with its corresponding factor in **post\_data\_factor** and added to **post\_data\_result**. This allows you to conveniently follow the sum of data item, each multiplied with some factor.

**6.927** **post\_data\_factor** *index factor\_0 factor\_1* ...

See **post\_data**.

**6.928** **post\_data\_result** *index result*

See **post\_data**.

**6.929 post\_element\_force** *index dir\_normal\_x dir\_normal\_y dir\_normal\_z  
dir\_shear0\_x dir\_shear0\_y dir\_shear0\_z dir\_shear1\_x dir\_shear1\_y  
dir\_shear1\_z middle\_x middle\_y middle\_z*

With this record you can calculate the normal force, shear force and moments in cross sections. Only cross sections at the side of elements are allowed; so that typically is the common side between two elements, or the side at the edge of a domain; a cross section through the interior of elements is not allowed. Below we will describe how you can select elements. For the combination of selected elements nodal forces will be used to determine cross section forces and moments.

The *middle\_x middle\_y middle\_z* should contain the exact middle coordinates of the cross section. You can use this **post\_element\_force** option however also to get the soil forces on the shaft or toe of a pile; then use a *middle\_x middle\_y middle\_z* point below the bottom of the pile.

The nodal force components in the *dir\_normal\_x dir\_normal\_y dir\_normal\_z* direction are summed to give a normal force *normal\_force*. The nodal force components in the *dir\_shear0\_x dir\_shear0\_y dir\_shear0\_z* direction are summed to give the first shear force *shear0\_force*. The nodal force components in the *dir\_shear1\_x dir\_shear1\_y dir\_shear1\_z* direction are summed to give the second shear force *shear1\_force*. The nodal force components in the *dir\_normal\_x dir\_normal\_y dir\_normal\_z* direction are multiplied with the distance in *dir\_shear0\_x dir\_shear0\_y dir\_shear0\_z* direction as measured from the *middle\_x middle\_y middle\_z* vector, and this is summed to give the first bending moment *moment0*. The nodal force components in the *dir\_normal\_x dir\_normal\_y dir\_normal\_z* direction are multiplied with the distance in *dir\_shear1\_x dir\_shear1\_y dir\_shear1\_z* direction as measured from the *dir\_shear0\_x dir\_shear0\_y dir\_shear0\_z* vector, and this is summed to give the first bending moment *moment1*. The results for the normal force, two shear forces and two moments will be placed in the record **post\_element\_force\_result**.

In 3D you need to specify the complete **post\_element\_force** record and you get the normal force, two shear forces and two bending moments in the **post\_element\_force\_result** record. The directions *dir\_shear0\_x dir\_shear0\_y dir\_shear0\_z* and *dir\_shear1\_x dir\_shear1\_y dir\_shear1\_z* should be perpendicular.

In 2D you need to specify only a partial record **post\_element\_force** as *index dir\_normal\_x dir\_normal\_y dir\_shear0\_x dir\_shear0\_y middle\_x middle\_y* and you get the normal force, one shear force and one bending moment in the **post\_element\_force\_result** record.

In 1D you need to specify only a partial record **post\_element\_force** as *index dir\_normal\_x middle\_x* and you get the normal force in the **post\_element\_force\_result** record.

You can restrict with **post\_element\_force\_geometry** with the same index that the **post\_element\_force** is only evaluated for nodes on a specific geometry. This **post\_element\_force** option always checks if the initial node location is located on this geometry (so not the location of moved nodes after displacement of the nodes).

You can restrict with **post\_element\_force\_group** with the same index that the **post\_element\_force** is only evaluated for certain element groups.

You can restrict with **post\_element\_force\_number** with the same index that the **post\_element\_force** is only evaluated for certain element numbers.

You can restrict with **post\_element\_force\_normal** with the same index that the **post\_element\_force** is only evaluated for elements in positive normal direction *dir\_normal\_x* *dir\_normal\_y* *dir\_normal\_z*. If you don't specify **post\_element\_force\_normal** elements on both sides will be used if present.

You can require by setting the *switch* in **post\_element\_force\_force** with the same index that also the external forces (like gravity and edge loads etc.) are added to the result.

You can require by setting the *switch* in **post\_element\_force\_inertia** with the same index that also the inertia forces is added to the result.

If you are not happy with the sign or units with which the forces are calculated, you can use a multiply factor in **post\_element\_force\_multiply\_factor** with the same index to get what you want.

Please realise that in calculation with groundwater the calculated forces contain the force due to effective stresses and also due to groundwater total pressure (pore pressure).

We now give some examples for a 2D vertical pile driven into the soil in a dynamic **inertia ...** calculation, and including gravity **force\_gravity ...** and an external force **force\_element\_edge ...** at the top of the pile. Below *x\_pile* is the x-coordinate at the middle of the pile, *y\_pile\_middle* is the y-coordinate at the middle of the pile, *y\_pile\_bottom* is the y-coordinate at the bottom of the pile and *pile\_group* is the group number of the pile.

The force in a cross section (force resulting from normal stress in cross section):

```
...
post_element_force 10 0. 1. 1. 0. x_pile y_pile
post_element_force_geometry 10 -pile_cross_section
post_element_force_group 10 pile_group
...
...
```

Here *pile\_cross\_section* is a geometry line through the cross section of the pile,

The force along the shaft (force resulting from shear stress along shaft):

```
...
post_element_force 10 0. 1. 1. 0. x_pile y_pile_bottom
```

```

post_element_force_geometry 10 -pile_shaft
post_element_force_group 10 pile_group
post_element_force_force 10 -yes
post_element_force_inertia 10 -yes
...

```

Here *pile\_shaft* is a geometry line containing only nodes of the pile shaft,

The force at the pile toe (force resulting from normal stress at pile tip):

```

...
post_element_force 10 0. 1. 1. 0. x_pile y_pile_bottom
post_element_force_geometry 10 -pile_toe
post_element_force_group 10 pile_group
post_element_force_force 10 -yes
post_element_force_inertia 10 -yes
...

```

Here *pile\_toe* is a geometry line containing only nodes of the pile toe,

The complete force on the pile:

```

...
post_element_force 10 0. 1. 1. 0. x_pile y_pile_bottom
post_element_force_geometry 10 -pile_complete
post_element_force_group 10 pile_group
post_element_force_force 10 -yes
post_element_force_inertia 10 -yes
...

```

Here *pile\_complete* is a geometry line containing all nodes of the pile,

Also see the example calculation **force14.dat** and **force17.dat**.

## 6.930 post\_element\_force\_force *index switch*

See **post\_element\_force**.

**6.931** `post_element_force_geometry` *index geometry\_item\_name geometry\_item\_index*

See `post_element_force`.

**6.932** `post_element_force_group` *index element\_group\_0 element\_group\_1 ...*

See `post_element_force`.

**6.933** `post_element_force_inertia` *index switch*

See `post_element_force`.

**6.934** `post_element_force_multiply_factor` *index multiply\_factor*

See `post_element_force`.

**6.935** `post_element_force_normal` *index switch*

Set *switch* to `-yes` if you want to select elements in positive normal direction. See `post_element_force`.

**6.936** `post_element_force_number` *index number\_0 number\_1 ...*

See `post_element_force`.

**6.937** `post_element_force_result` *index normal\_force shear0\_force shear1\_force moment0 moment1*

See `post_element_force`.

**6.938** `post_global` *switch*

With this `post_global` you can ask for global information to be determined if you set *switch* to `-yes`. The following information will then be determined:

- **-post\_bounda\_force\_summed** (total force following from **-bounda\_force** records, number of principal dofvalues)
- **-post\_element\_mass\_summed** (total global mass)
- **-post\_element\_summed** (total number of elements)
- **-post\_element\_volume\_summed** (total elements volume without empty elements)
- **-post\_group\_summed** (total number of elements in group 0, group 1, etc.)
- **-post\_materi\_inertia\_summed** (sum of material nodal inertia, so of **node\_inertia**)
- **-post\_slide\_force\_summed** (sum of slide forces in global axes, so of **node\_slide\_force**)
- **-post\_node\_summed** (total number of nodes)
- **-post\_node\_dof\_average** (average values for dof's)
- **-post\_node\_dof\_maximum** (maximum values for dof's)
- **-post\_node\_dof\_minimum** (minimum values for dof's)
- **-post\_force\_edge\_summed** (total force following from **-force\_edge** integrated over edges in x,y,z directions, *number\_of\_space\_dimensions* values)
- **-post\_force\_edge\_normal\_summed** (total force following from **-force\_edge\_normal** integrated over edges in x,y,z directions, *number\_of\_space\_dimensions* values)
- **-post\_force\_edge\_projected\_summed** (total force following from **-force\_edge\_projected** integrated over edges in x,y,z directions, *number\_of\_space\_dimensions* values)
- **-post\_support\_edge\_normal** (total force following from **-support\_edge\_normal** integrated over edges in x,y,z directions, *number\_of\_space\_dimensions* values)
- **-post\_solver\_diagonal\_minimum\_value** (minimum diagonal term total matrix, only for pardiso solver)
- **-post\_solver\_diagonal\_minimum\_node** (node number at which the minimum value is found)
- **-post\_solver\_diagonal\_maximum\_value** (maximum diagonal term total matrix, only for pardiso solver)
- **-post\_solver\_diagonal\_maximum\_node** (node number at which the maximum value is found)
- **-post\_solver\_diagonal\_ratio** (ratio maximum/minimum diagonal terms total matrix, only for pardiso solver)
- **-post\_solver\_iterations** (total number of iterations of iterative linear equation solver, only for bicg solver)

If you set *switch* to **-no** then the information will not be determined (this saves a little bit of computer time). Default, if **post\_global** is not specified, *switch* to **-yes**.

**6.939 post\_group\_volume\_summed** *volume\_group\_0 volume\_group\_1*  
 ...

This record will be filled with the total volume of the elements in each group. So *volume\_group\_0* is the summed volume of the elements in element group 0, etc.

**6.940 post\_integrate** *index data\_item\_name data\_item\_index data\_item\_number*  
 ...

Here you can specify results that should be integrated over time. The integrated results will be placed in the **post\_integrate\_result** record with the same index.

An example looks like:

```
...
groundflow_pressure
groundflow_velocity
end_initia
...
post_node 1 -average -geometry_line 4
...
post_integrate 3 -post_node_result 1 -gvly
...
...
```

Here the **post\_node** record first takes care that the average groundflow y-velocity at nodes on a line are determined, among other dof's. The **post\_integrate** record integrates that average groundflow y-velocity over time. In this way the total groundflow debit volume over a line is registered.

**6.941 post\_integrate\_result** *index result*

See **post\_integrate**.

**6.942 post\_line** *index x\_0 y\_0 z\_0 x\_1 y\_1 z\_1*

This record specifies a line in space for which the average or sum of the dof values will be calculated. The values are placed in a record **post\_line\_dof** with the same *index*. Internally in TOCHNOG, **post\_point** records are used to evaluate the dof's on the line.

In 1D only  $x_0$  and  $x_1$  should be specified, etc.. In the example below, the average of the  $x$ -velocity between the points (3,1) and (3,7) will be printed

```
...
number_of_space_dimensions 2
materi_velocity
...
end_data
...
post_line 1 3. 1. 3. 7.
...
print_filter 0 -post_line_dof 1 -velx
...
control_timestep 1 1. 100.
control_print 1 -post_line_dof
```

The coordinates are defined in the initial mesh. See also: **post\_line\_n** and **post\_line\_operat**.

#### 6.943 **post\_line\_operat** *index operat*

If *operat* is set to **-average** then the average is calculated for the **post\_line** record with the same index. If *operat* is set to **-sum** then the sum is calculated for the **post\_line** record with the same index.

If this **post\_line\_operat** is not specified, then *operat* is set to **-average**.

#### 6.944 **post\_line\_dof** *index dof\_0 dof\_1 ...*

Average dofvalues at a selected line. See **post\_line**.

#### 6.945 **post\_line\_dof\_calcul** ...

See **post\_calcul**.

#### 6.946 **post\_line\_n** *index n*

Use  $n$  **post\_point** records to evaluate the dof's along the line. Default  $n$  is 5. See **post\_line**.

#### 6.947 **post\_node** *index data\_item operat geometry\_entity\_name geometry\_entity\_index*

If *operat* is set to **-sum**, results for the nodal *data\_item* are summed. For example, you can take for *data\_item* the **-node\_rhside** and for *operat* you take **-sum** so that the total external force on a boundary is determined.

If *operat* is set to **-average**, results for the nodal *data\_item* are averaged.

If *data\_item* is set to **-node\_rhside** and *operat* is set to **-moment**, the moment is determined around the origin (x=0,y=0) in a 2D calculation; this is done by calculating in the nodes the tangential force extracted from **-node\_rhside** and multiplying it with the radial distance from the origin.

This operation is done for nodes which are placed on the geometrical entity *geometry\_entity\_name* *geometry\_entity\_index*. Instead of a geometrical entity you can also use **-all** to tell that all nodes should be used. Instead of a geometrical entity you can also use **-ra .. -ra** to tell that the nodes of the range should be used.

The result of this **post\_node** record is put into the **post\_node\_result** record (with the same *index*).

#### 6.948 **post\_node\_factor** *index factor*

You can multiply the result of **-post\_node** with *factor*. Default, if **post\_node\_factor** is not specified, we take *factor* equal to 1.

#### 6.949 **post\_node\_result** *index result\_0 result\_1 ...*

See **post\_node**.

#### 6.950 **post\_node\_rhside\_fixed** *value\_0 value\_1 ...*

This record will be filled with the sum of **node\_rhside** for those dof's which are prescribed (eg with a **bounda\_dof**). For example, in a calculation with only velocities (displacements) as primary dof's, this record contains the sum of the reaction force at the nodes in which the velocity is prescribed. Values are only filled for principal dof's (materi velocity, groundflow pressure, condif temperature, ...).

#### 6.951 **post\_node\_rhside\_free** *value\_0 value\_1 ...*

Same as **post\_node\_rhside\_fixed**, now for free values however. For example, in a calculation with only velocities (displacements) as primary dof's, this record contains the sum of the unbalance force at the nodes in which the velocity is not prescribed.

#### 6.952 **post\_node\_rhside\_ratio** *ratio*

This record gives during a calculation a measure for the inaccuracy of the calculation. For each primary dof the ratio between the size of the right-hand-side (nodal forces or nodal fluxes ...) in fixed nodes and free nodes.

If the size for the fixed nodes is below 1.e-10 the *ratio* is directly filled the result for free nodes. See also **post\_node\_rhside\_ratio\_dof\_type**.

#### 6.953 **post\_node\_rhside\_ratio\_dof\_type** *dof\_type\_0 ...*

With this option you can specify a list of doftypes which should be used in the calculation of the **post\_node\_rhside\_ratio** result. For example, if both **groundflow\_pressure** and **condif\_temperature** are initialised, then you can use only the groundflow pressure in the accuracy ratio determination by specifying **post\_node\_rhside\_ratio\_dof\_type -groundflow\_pressure**.

If **post\_node\_rhside\_ratio\_dof\_type** is not specified and **materi\_velocity** is initialised then automatically **post\_node\_rhside\_ratio\_dof\_type -materi\_velocity** will be used.

#### 6.954 **post\_node\_rhside\_ratio\_method** *method*

By setting *method* to **-post\_node\_rhside\_free** the *ratio* is directly filled with **post\_node\_rhside\_free**. Default, when this **post\_node\_rhside\_ratio\_method** record is not specified, the default definition as specified in **post\_node\_rhside\_ratio** is used,

#### 6.955 **post\_point** *index x y z*

This record specifies a point in space for which dof values will be calculated. The values are placed in a record **post\_point\_dof** with the same *index*. The values are obtained by determining in which element the point is located and then using the element's interpolation functions. In 1D only *x* should be specified, etc.. The coordinates are defined in the initial mesh. This option is only available for isoparametric elements.

### 6.956 **post\_point\_element\_group** *index element\_group*

Limit the search for the element in which the post point with the same *index* is located to the specified *element\_group*.

### 6.957 **post\_point\_dof** *index dof\_0 dof\_1 ...*

Unknown values at a selected point. See **post\_point**.

### 6.958 **post\_point\_dof\_calcul** ...

See **post\_calcul**.

### 6.959 **post\_point\_eps\_iso** *index eps*

Tolerance with which a **post\_point** is accepted to be part of an element. The default value is 1.e-3. You can increase the default value if a **post\_point** is exactly on or over the border of the mesh, so that the **post\_point** may be not found; typically try 0.1 or so.

### 6.960 **post\_point\_move** *index switch*

If *switch* is set to **-yes** the **post\_point** with the same index will be moved along with the velocity field. Thus, with this option you can follow with a **post\_point** the dof's of a material particle.

Please realise that this option should only be used if **materi\_velocity** is initialised in the initialisation part.

### 6.961 **post\_quadrilateral** *index x\_0 y\_0 z\_0 x\_1 y\_1 z\_1 x\_2 y\_2 z\_2 x\_3 y\_3 z\_3*

This record specifies a quadrilateral in space for which the average of the dof values will be calculated. The values are placed in a record **post\_quadrilateral\_dof** with the same *index*. Internally in TOCHNOG, **post\_point** records are used to evaluate the dof's on the quadrilateral. In 2D only *x\_0 y\_0*, *x\_1 y\_1*, etc. should be specified. The coordinates are defined in the initial mesh. See also: **post\_quadrilateral\_n**.

**6.962** `post__quadrilateral__dof` *index dof\_0 dof\_1 ...*

Average dof values at a selected quadrilateral. See `post__quadrilateral`.

**6.963** `post__quadrilateral__dof__calcul` ...

See `post__calcul`.

**6.964** `post__quadrilateral__element__group` *index element\_group*

Select the specific element group from which the dof values should be taken.

**6.965** `post__quadrilateral__n` *index n*

Use *n* `post__point` records in each direction to evaluate the dof's along the quadrilateral. Default *n* is 5. See `post__quadrilateral`.

**6.966** `post__strain__volume__absolute` *index volume\_increase\_absolute*

This record will hold after the calculation the absolute volume increase summed over the elements that are selected in the `strain__volume__element`, `strain__volume__element__group` and `strain__volume__geometry` records (with the same index).

The actual volume increase which you will find in this `post__strain__volume__absolute` record will depend on the relative volume strain or absolute volume increase that you specified, but also on stiffnesses of neighboring zones, boundary conditions, etc.

You can use this `post__strain__volume__absolute` result to decide to manually change the specified relative volume strain or absolute volume increase and rerun the calculation.

**6.967** `post__strain__volume__initial` *index volume\_initial*

Initial volume of selected elements.

**6.968** `post__strain__volume__relative` *index volume\_strain\_relative*

Relative volume strain percentage. Otherwise the same as `post__strain__volume__absolute`.

### 6.969 `print__apply` *switch*

If *switch* is set to **-no**, then all **control\_\_print\_\_\*** records will not be applied. Default, if **print\_\_apply** is not specified, *switch* is set to **-yes**.

### 6.970 `print__arithmetic` *switch*

If *switch* is set to **-yes**, all evaluated arithmetics will be printed. See the start of the data part for an explanation about arithmetics. The printing will be done to the file **tochnog\_\_arithmetic.txt**.

### 6.971 `print__control` *switch*

If *switch* is set to **-yes**, the control index being evaluated will be printed. Handy for keeping track on what the program is doing.

### 6.972 `print__data__name` *switch*

If *switch* is set to **-yes**, all possible data names will be printed. The printing will be done to the file **tochnog\_\_data\_\_name.txt**.

This is convenient to search in the **tochnog\_\_data\_\_name.txt** file fast for options. For example under linux to search all options which have the word **group** in it do **grep group tochnog\_\_data\_\_name.txt**.

The possible data names may include also internal names that Tochnog uses during the calculation; so for each name you can check this users manual if it is a name that you can use as input in the input file, or not.

### 6.973 `print__database__calculation` *switch*

If *switch* is set to **-yes**, the database will be written after successful completion of a calculation to the file **name.dbs**, where *name* is the name of the input file. If *switch* is set to **-no**, the database will not be written.

Default, *switch* is set to **-yes**.

### 6.974 `print__define` *switch*

If *switch* is set to **-yes**, all evaluated defines will be printed. See the start of the data part for an explanation about defines. The printing will be done to the file **tochnog\_\_define.txt**.

### 6.975 `print_element_geometry_present switch`

See `element_geometry_present`. See also `print_element_geometry_present_node_type`. Default *switch* is set to **-no**.

### 6.976 `print_element_geometry_present_node_type node_type`

If *node\_type* is set to **-node\_start\_refined** the values of **-node\_start\_refined** are used. If *node\_type* is set to **-node** the values of **-node** are used. If *node\_type* is set to **-plus\_displacement** the values of **-node** plus nodal displacements. Default *node\_type* is set to **-node\_start\_refined**.

### 6.977 `print_failure switch`

If *switch* is set to **-yes** then failure of elements due to one of the failure criteria (**group\_materi\_failure\_rupture**, etc.) will be reported.

### 6.978 `print_filter index data_item_name data_item_index number_0 number_1 ...`

The data selected in the records **control\_print**, **control\_print\_dof**, **control\_print\_dof\_rhside** and **control\_print\_element** will be filtered at output. Thus only a limited amount of data will actually be printed. Here *data\_item\_name* is the name of the data item to be filtered, e.g. *data\_item\_name* is **-node\_dof**. *data\_item\_index* is the index of the *data\_item\_name* record which passes the filter. If, for example, *data\_item\_index* is 3 then only index 3 passes the filter. If *data\_item\_index* is **-all** then all indices pass the filter. If, for example, *data\_item\_index* is **-geometry\_line 3** (valid if *data\_item\_name* is **-node** or another nodal item) then only records with coordinates located on line 3 pass the filter. If, for example, *data\_item\_index* is **-geometry\_line 3** (valid if *data\_item\_name* is **-element** or another element item) then only element with at least one coordinate located on line 3 pass the filter. If, for example, *data\_item\_index* is **-ra ... -ra** then indices in this range pass the filter. If, for example, *data\_item\_index* is **-macro 4** and *data\_item\_name* is data valid at a node (or element), then only nodes (or elements) generated by the macro number 4 pass the filter (see **control\_mesh\_macro \*** for macro's). If, for example, *data\_item\_index* is **-macro -none** and *data\_item\_name* is data valid at a node (or element) then only nodes (or elements) not generated by any macro pass the filter (see **control\_mesh\_macro \*** for macro's).

For example, if *number\_0* is 3 then the fourth value of a record passes the filter. If *number\_0* is **-all** the whole record passes the filter. If, for example, *number\_0* is **-velx** while *data\_item\_name* is **-node\_dof** then only *x*-velocities pass the filter.

Some examples are

```

print_filter 1 -node_dof -all -temp -sigxx (temperatures and xx-stresses)
print_filter 2 -node -geometry_line 3 0 (x-coordinates on line 3)

```

With **control\_print\_filter** you can select if the records **control\_print**, **control\_print\_dof** or **control\_print\_dof\_rhside** (with the same index) should use specific filters (specify the indices of the filter for *print\_filter\_index*), should use all filters (specify **-all** for *print\_filter\_index*), or should use no filter at all (specify **-none** for *print\_filter\_index*). Default, if **control\_print\_filter** is not specified, all filters will be used for a print option.

Example:

```

print_filter 1 -node_dof ...
print_filter 2 -node_dof_all ...
print_filter 3 ...
...
control_print_dof 10 ...
control_print_filter 10 1 2 (only use filter 1 and 2)
...
control_timestep 20 ...
control_print 20 ...
control_print_filter 20 -all (use all filters)

```

All used filters are placed in-line for a data item; thus only data which passes all used filters for that data item will be printed.

### 6.979 **print\_gid\_calculation** *switch*

If you set *switch* to **-yes** the gid files will be printed at the end of the calculation. If you set *switch* to **-no** the gid files will not be printed at the end of the calculation. Default, if *switch* is not specified, it is set to **-yes**.

### 6.980 **print\_frd\_freecad** *switch*

See **control\_print\_frd\_freecad** , but now for all frd printing however. If both **control\_print\_frd\_freecad** and **print\_frd\_freecad** are present, the **control\_print\_frd\_freecad** dictates what happens for the specific control index.

If both **print\_frd\_freecad** and **control\_print\_frd\_freecad** are not specified the *switch* is set to **-no**.

### 6.981 `print_frd_prepomax switch`

See `control_print_frd_prepomax` , but now for all frd printing however. If both `control_print_frd_prepomax` and `print_frd_prepomax` are present, the `control_print_frd_prepomax` dictates what happens for the specific control index.

If both `print_frd_prepomax` and `control_print_frd_prepomax` are not specified the *switch* is set to **-no**.

### 6.982 `print_gid_contact_spring2 number_of_nodes`

Set *number\_of\_nodes* to 2 if you want to draw `contact_spring2` with two nodes, and to 1 if you want to draw `contact_spring2` with one node. Default, if `print_gid_contact_spring2` is not specified, then 1 is used for *number\_of\_nodes*.

### 6.983 `print_gid_coord switch`

If *switch* is set to **-yes** the coordinates of nodes is plotted in gid.

### 6.984 `print_gid_define switch`

If *switch* is set to **-yes** defined names will be used i.s.o. geometry names (when a geometry is defined as a name with `start_define ... end_define`). If *switch* is set to **-no** that will not be done. Default, if *switch* is not specified, *switch* is set to **-yes**.

### 6.985 `print_gid_group switch`

If *switch* is set to **-yes** the element groups are plotted in gid as result field; in gid you can do a `contour_fill` to visualize this result field. If *switch* is set to **-no** the element groups are not plotted in gid as result. Default *switch* is set to **-yes**.

### 6.986 `print_gid_mesh_activate_gravity switch`

See also `mesh_activate_gravity_time`.

### 6.987 `print_gid_node_method method`

See `print_gid_node_method`.

### 6.988 **print\_gid\_spring2** *number\_of\_nodes*

Set *number\_of\_nodes* to 2 if you want to draw **spring2** with two nodes, and to 1 if you want to draw **spring2** with one node. Default, if **print\_gid\_spring2** is not specified, then 1 is used for *number\_of\_nodes*.

### 6.989 **print\_gid\_smooth\_dof** *dof\_0 dof\_1 ...*

This option allows you to smooth results in gid files. With *dof\_0 dof\_1 ...* you specify the dof's to be smoothed. As a special option you can specify **-all** so that all dof's will be smoothed.

The smoothing is done a number of times, with increasing smooth results. You can specify this number of times with the optional **print\_gid\_smooth\_n**; if you don't specify this optional number of smoothings it is done 10 times.

### 6.990 **print\_gid\_smooth\_n** *index number\_of\_smoothings*

See **print\_gid\_smooth\_dof**.

### 6.991 **print\_group\_data** *dataitem\_name\_0 dataitem\_name\_1 ...*

Print in the gid files **group\_\*** data items for isoparametric finite elements. As a typical example use **-group\_materi\_elasti\_young**; then you get in the gid plot what the young model distribution is for isoparametric finite elements in the mesh.

For different values of group data in integration points, the value of the last integration point will be used.

For elements which do not have a specific group data item a value 0 will be plotted. Tochnog sets the gid group data information in the timesteps, so only after timesteps have been taken you will see meaningful results for the group data in gid plots.

The values will also be placed in the **element\_print\_group\_data** records.

### 6.992 **print\_gmsh\_calculation** *switch*

If you set *switch* to **-yes** the gmsh files will be printed at the end of the calculation. If you set *switch* to **-no** the gmsh files will not be printed at the end of the calculation. Default, if *switch* is not specified, it is set to **-no**.

### 6.993 `print_gmsh_dummy` *switch*

See `control_print_gmsh_dummy`. This `print_gmsh_dummy` holds for all gmsh printing, unless it is overruled by a `control_print_gmsh_dummy`.

### 6.994 `print_gmsh_node_method` *method*

See `print_gmsh_node_method`.

### 6.995 `print_mesh_dof` *dof\_0 dof\_1 ...*

This option allows you to print results for dof's (temperatures, groundflow pressures, ...) in a first calculation and use these results later in a second calculation as boundary conditions. This comes handy when you need to run the second calculation multiple times, and the results for the printed dof's can be taken from the first calculation. In this way, the computing time of the second calculation can be smaller, and also a different FE mesh can be used in the first calculation and the second calculation for the different doffields.

In the first calculation you can print the dof's with the command `print_mesh_dof`; the results will be printed in the file `print_mesh_dof.txt`. The *dof\_0 dof\_1 ...* of `print_mesh_dof` specify the dof's which will be printed. In the first calculation printing of the dof's to the file `print_mesh_dof.txt` will actually be done for when *switch* is set to `-yes` in `control_print_mesh_dof`.

For the second calculation rename the file `print_mesh_dof.txt` into `bounda_mesh_dof.txt`. You can specify which of the dof's in the file `bounda_mesh_dof.txt` will actually be used a prescribed value ('boundary condition') with the *dof\_0 dof\_1 ...* of `bounda_print_mesh_dof`. You can restrict the nodes to which this will be done by `bounda_print_mesh_dof_geometry` (please realise using a geometry point with a very large tolerance in combination with `geometry_element_group` you can effectively select the geometry formed by an element group).

The FE meshes as used in the first calculation and in the second calculation need not be the same, and are also allowed to vary in time (in building processes, excavations, etc.). Nodes from the second mesh will be located in the first mesh, and doffields will be interpolated from the first mesh to the second mesh. In case a node from the second mesh is not inside any isoparametric element of the first mesh, the value for the dof's as specified in the optional `bounda_print_mesh_dof_values` will be used. In `bounda_print_mesh_dof_values` you need to specify values for each and every dof that was specified with `print_mesh_dof` in the first calculation. If the node of the second mesh cannot be found in the first mesh and also `bounda_print_mesh_dof_values` is not specified then the dof's will be taken from the closest node of the first mesh.

Results for the second mesh will be linearly interpolated in time from results of the first mesh.

Example first calculation in which only a temperature field is calculated:

```
echo -yes
number_of_space_dimensions 2
condif_temperature
end_initia
...
print_mesh_dof -temp
...
control_timestep 10 ...
control_print_mesh_dof 10 -yes (print in print_mesh_dof.txt)
...
```

Example second calculation in which the temperature field calculated in the first calculation is imposed:

```
echo -yes
number_of_space_dimensions 2
condif_temperature
materi_velocity
materi_displacement
materi_stress
end_initia
...
bounda_print_mesh_dof -temp
bounda_print_mesh_dof_values 20. (read from bounda_mesh_dof.txt)
...
```

#### 6.996 print\_node\_geometry\_present *switch*

See `node_geometry_present`. See also `print_node_geometry_present_node_type`. Default *switch* is set to `-no`.

#### 6.997 print\_node\_geometry\_present\_node\_type *node\_type*

If *node\_type* is set to `-node_start_refined` the values of `-node_start_refined` are used. If *node\_type* is set to `-node` the values of `-node` are used. If *node\_type* is set to `-plus_displacement` the values of `-node` plus nodal displacements. Default *node\_type* is set to `-node_start_refined`.

#### **6.998   `print__precision` *number\_of\_values***

With *number\_of\_values* you can set for all printing how many values will be used at printing. For example, setting *number\_of\_values* to **4** the internal tochnog double **98.123456789** will be printed as **98.12** when using **control\_\_print**, **control\_\_print\_\_gid** etc.

#### **6.999   `print__tecplot__calculation` *switch***

If you set *switch* to **-yes** the tecplot files will be printed at the end of the calculation. If you set *switch* to **-no** the tecplot files will not be printed at the end of the calculation. Default, if *switch* is not specified, it is set to **-yes**.

#### **6.1000   `print__vtk__calculation` *switch***

If you set *switch* to **-yes** the vtk files will be printed at the end of the calculation. If you set *switch* to **-no** the vtk files will not be printed at the end of the calculation. Default, if *switch* is not specified, it is set to **-yes**.

#### **6.1001   `print__vtk__coord` *switch***

If *switch* is set to **-yes** the coordinates of nodes is plotted in vtk.

#### **6.1002   `print__vtk__group` *switch***

If *switch* is set to **-yes** the element groups are plotted in vtk as result field. If *switch* is set to **-no** the element groups are not plotted in vtk as result. Default *switch* is set to **-yes**.

#### **6.1003   `print__vtk__node__method` *method***

See **print\_\_vtk\_\_node\_\_method**.

#### **6.1004   `print__where` *switch***

If *switch* is set to **-yes**, information will be printed about the tasks that tochnog is performing (evaluation boundary conditions, loop over elements, etc.).

This is convenient for very large calculations, to see what is being done and how the calculation proceeds.

### 6.1005 **processors** *nproc*

With this record you can set the number of shared memory CPUs you want to use (*nproc*). If your TOCHNOG implementation does not allow for more processors, this record is ignored. In fact, not the number of processors but the number of threads is set (that is, if you use 2 threads while your system only supports 1 processor than those threads are split over that single processor).

Error messages may become confusing when you use more than one processor.

Default *nproc* is 1.

### 6.1006 **processors\_\_maximum** *switch*

If *switch* is set to **-yes**, the **processors** record will be set to the maximum number as allowed by your computer.

Default *switch* is set to **-yes**. This **processors\_\_maximum** record will not be used if the **processors** record is specified.

### 6.1007 **processors\_\_partition** *npartition*

The element loop is paralised as follows. The master process gives away small amounts of the total number of elements to child processes, and if a child process is ready it gets a new small amount of the master process. In fact, a child process gets each time an amount of  $\frac{nelement}{npartition*processors}$  where *nelement* is the number of elements, *npartition* is specified in **processors\_\_partition**, and *processors* is specified in **processors**. Default, if **processors\_\_partition** is not specified, we set *npartition* to 1.

### 6.1008 **repeat\_\_save\_\_result** *index result\_0 result\_1 ...*

See **control\_\_repeat\_\_save**. The index is the number of repetition (index 0 is repeat 0, index 1 is repeat 1, etc.)

### 6.1009 **repeat\_\_save\_\_calculate\_\_result** *average\_0 variance\_0 average\_1 variance\_1 ...*

See **control\_\_repeat\_\_save\_\_calculate**.

#### 6.1010 **safety\_slip\_circle\_grid\_middle** *index x\_first y\_first x\_last y\_last*

This record specifies a grid with middles of a circle for safety factor calculations. With *x\_first y\_first* you specify the first middle. With *x\_last y\_last* you specify the last middle. With **safety\_slip\_circle\_grid\_middle\_n** you specify the number of middles that should be evaluated in the safety calculation; all middles together form a equidistant grid between *x\_first y\_first* and *x\_last y\_last*.

As a special option you can only specify *x\_first y\_first* and not specify **safety\_slip\_circle\_grid\_middle\_n**; then only one middle *x\_first y\_first* will be evaluated for the circle in the safety calculation.

See also **control\_safety\_slip**.

#### 6.1011 **safety\_slip\_circle\_grid\_middle\_n** *index n*

See **safety\_slip\_circle\_grid\_middle**.

#### 6.1012 **safety\_slip\_circle\_grid\_radius** *index r\_first r\_last*

This record specifies the radius of a circle for safety factor calculations.

With *r\_first* you specify the first radius. With *r\_last* you specify the last radius. With **safety\_slip\_circle\_grid\_radius\_n** you specify the number of radius that should be evaluated in the safety calculation; all radius to be evaluated will be put equidistant between *r\_first* and *r\_last*.

As a special option you can only specify *r\_first* and not specify **safety\_slip\_circle\_grid\_radius\_n**; then only one radius *r\_first* will be evaluated for the circle in the safety calculation.

#### 6.1013 **safety\_slip\_circle\_grid\_radius\_n** *index n*

See **safety\_slip\_circle\_grid\_radius**.

#### 6.1014 **safety\_slip\_circle\_grid\_result** *index x y r safety\_factor*

This record will after the calculation be filled with the middle, radius and safety factor for the critical surface (for the slip circles with the same index).

#### 6.1015 **safety\_slip\_circle\_grid\_segment\_n** *index n*

With this record you can specify how many segments in the circle will be used in the integration of the safety factor. A high number of segments gives more accuracy but is time consuming. A low number of segments is less accurate but fast. Default, if **safety\_slip\_circle\_grid\_segment\_n** is not specified, then 90 segments will be used.

#### 6.1016 **safety\_slip\_circle\_line\_middle** *index x\_first y\_first x\_last y\_last*

This record specifies a line with middles of a circle for safety factor calculations. With *x\_first y\_first* you specify the first middle. With *x\_last y\_last* you specify the last middle. With **safety\_slip\_circle\_line\_middle\_n** you specify the number of middles that should be evaluated in the safety calculation; all middles together form a equidistant line between *x\_first y\_first* and *x\_last y\_last*.

As a special option you can only specify *x\_first y\_first* and not specify **safety\_slip\_circle\_line\_middle\_n**; then only one middle *x\_first y\_first* will be evaluated for the circle in the safety calculation.

See also **control\_safety\_slip**.

#### 6.1017 **safety\_slip\_circle\_line\_middle\_n** *index n*

See **safety\_slip\_circle\_line\_middle**.

#### 6.1018 **safety\_slip\_circle\_line\_radius** *index r\_first r\_last*

This record specifies the radius of a circle for safety factor calculations.

With *r\_first* you specify the first radius. With *r\_last* you specify the last radius. With **safety\_slip\_circle\_line\_radius\_n** you specify the number of radius that should be evaluated in the safety calculation; all radius to be evaluated will be put equidistant between *r\_first* and *r\_last*.

As a special option you can only specify *r\_first* and not specify **safety\_slip\_circle\_line\_radius\_n**; then only one radius *r\_first* will be evaluated for the circle in the safety calculation.

#### 6.1019 **safety\_slip\_circle\_line\_radius\_n** *index n*

See **safety\_slip\_circle\_line\_radius**.

#### 6.1020 **safety\_slip\_circle\_line\_result** *index x y r safety\_factor*

This record will after the calculation be filled with the middle, radius and safety factor for the critical surface (for the slip circles with the same index).

#### 6.1021 **safety\_slip\_circle\_line\_segment\_n** *index n*

With this record you can specify how many segments in the circle will be used in the integration of the safety factor. A high number of segments gives more accuracy but is time consuming. A low number of segments is less accurate but fast. Default, if **safety\_slip\_circle\_line\_segment\_n** is not specified, then 90 segments will be used.

#### 6.1022 **safety\_slip\_combined\_linear** *index x\_first,0 y\_first,0 x\_first,1 y\_first,1 ... x\_last,0 y\_last,0 x\_last,1 y\_last,1 ...*

This record specifies combined linear lines along which the safety factor should be calculated.

All data with *first* specifies the first combined linear line. The *x\_first,0 y\_first,0* specifies the first point of the first line piece of the first combined linear line, the *x\_first,1 y\_first,1* specifies the second point of the first line piece of the first combined linear line The *x\_first,2 y\_first,2* specifies the first point of the second line piece of the first combined linear line, the *x\_first,3 y\_first,3* specifies the second point of the second line piece of the first combined linear line etc.

All data with *last* specifies the last combined linear line. The *x\_last,0 y\_last,0* specifies the first point of the first line piece of the last combined linear line, the *x\_first,1 y\_first,1* specifies the second point of the first line piece of the last combined linear line The *x\_last,2 y\_last,2* specifies the first point of the second line piece of the last combined linear line, the *x\_first,3 y\_first,3* specifies the second point of the second line piece of the last combined linear line etc. This last combined linear line should have an equal number of points as the first combined linear line.

With **safety\_slip\_combined\_linear\_n** you specify the number of combined linear lines that should be evaluated in the safety calculation; all combined linear lines to be evaluated will be put equidistant between the first combined linear line and the second combined linear line.

As a special option you can only specify data for the first combined linear line, and specify not data for the last combined linear line and not **safety\_slip\_combined\_linear\_n**; then only one combined linear line will be used.

See also **control\_safety\_slip**.

**6.1023 safety\_slip\_combined\_linear\_n** *index n*

See **safety\_slip\_combined\_linear**.

**6.1024 safety\_slip\_combined\_linear\_result** *index x\_0 y\_0 x\_1 y\_1 ... safety\_factor*

This record will after the calculation be filled with the combined linear line for the critical surface (for the combined linear lines circles with the same index).

**6.1025 safety\_slip\_combined\_linear\_segment\_n** *index n*

With this record you can specify how many segments in a line piece of a combined linear line will be used in the integration of the safety factor. A high number of segments gives more accuracy but is time consuming. A low number of segments is less accurate but fast. Default, if **safety\_slip\_combined\_linear\_segment\_n** is not specified, then 10 segments will be used.

**6.1026 safety\_slip\_ellipsoide** *index middle\_x\_first middle\_y\_first middle\_z\_first base1\_x\_first base1\_y\_first base1\_z\_first base2\_x\_first base2\_y\_first base2\_z\_first a\_first b\_first c\_first middle\_x\_last middle\_y\_last middle\_z\_last base1\_x\_last base1\_y\_last base1\_z\_last base2\_x\_last base2\_y\_last base2\_z\_last a\_last b\_last c\_last*

This record specifies a 3D ellipsoide for which the safety factor should be calculated. The ellipsoide equation is  $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$ , where  $x$ ,  $y$  and  $z$  are local coordinates in the ellipsoide. The ellipsoide is specified by 12 parameters in tochnog.

All parameters with *first* specifies the first ellipsoide. The *middle\_x\_first middle\_y\_first middle\_z\_first* specifies the ellipsoide middle (for which the local coordinates are 0;  $x = 0$ ,  $y = 0$ ,  $z = 0$ ). The *base1\_x\_first base1\_y\_first base1\_z\_first* specifies the direction of the local  $x$  axes in space. The *base2\_x\_first base2\_y\_first base2\_z\_first* specifies the direction of the local  $y$  axes in space. Tochnog determines automatically the direction of the local  $z$  axes in space. The  $a b c$  specifies the radii in respective the local  $x$ ,  $y$  and  $z$  direction.

All parameters with *last* specifies the last ellipsoide.

With **safety\_slip\_ellipsoide\_n** you specify the number of variations that should be used for each of the specified ellipsoids parameters. All parameters will be interpolated between the values specified for the first and last ellipsoide. In case you want to keep a parameter fixed, thus it should not be varied, simply specify an equal value for the parameter in the first and last ellipsoide.

As a special option you can only specify parameters for the first ellipsoide, and specify not parameters for the last ellipsoide.

See also **control\_safety\_slip**.

#### 6.1027 **safety\_slip\_ellipsoide\_method** *index method*

The normal on the ellipsoide surface is uniquely defined, so that the normal stresses are uniquely defined. The slip direction in the surface is not uniquely defined however. Below several possibilities are listed.

If *method* is set to **-safety\_slip\_ellipsoide**, then the ellipsoide local x direction will be used as slip direction (to be more precise, the projections on the ellipsoide surface will be used everywhere).

If *method* is set to **-materi\_displacement** or **-materi\_velocity\_integrated**, then the last calculated displacements will be used as slip direction (to be more precise, the projections on the ellipsoide surface will be used everywhere).

If *method* is set to **-materi\_velocity**, then the last calculated velocities will be used as slip direction (to be more precise, the projections on the ellipsoide surface will be used everywhere).

Default, if **safety\_slip\_ellipsoide\_method** is not specified, *method* is set to **-safety\_slip\_ellipsoide**.

#### 6.1028 **safety\_slip\_ellipsoide\_n** *index n*

See **safety\_slip\_ellipsoide**.

#### 6.1029 **safety\_slip\_ellipsoide\_result** *index middle\_x middle\_y middle\_z base1\_x base1\_y base1\_z base2\_x base2\_y base2\_z a b c safety\_factor*

This record will after the calculation be filled with the ellipsoide for the critical surface and the safety factor.

#### 6.1030 **safety\_slip\_ellipsoide\_segment\_n** *index n*

With this record you can specify how many segments in an ellipsoide will be used in the integration of the safety factor. The ellipsoide is internally in tochnog integrated in a local  $\phi$  and  $\theta$  direction, over **safety\_slip\_combined\_linear\_segment\_n** segments each. A high number of segments gives more accuracy but is time consuming. A low number of

segments is less accurate but fast. Default, if **safety\_slip\_ellipsoide\_n** is not specified, then 90 segments will be used.

### 6.1031 **safety\_slip\_grd** *index switch*

If *switch* is set to **-yes**, Tochnog will read a slip surface from the file *index.grd*. The file is in .grd format, as used by the **surfer** program from **Golden Software**. Thus the format is:

```

DSAA
nx ny
xmin xmax
ymin ymax
zmin zmax
... (for first y specify z values for all x)
... (for second y specify z values for all x)
...

```

This **safety\_slip\_grd** is only available in 3D.

### 6.1032 **safety\_slip\_grd\_method** *index method*

With this record you can specify with which method the slip direction is chosen (this is the direction in which the slip shear force will be determined, to calculate the safety factor).

If *method* is set to **-safety\_slip\_grd\_direction** the direction specified in **-safety\_slip\_grd\_direction** will be used. If *method* is set to **-materi\_velocity** the last calculated **-materi\_velocity** directions will be used. If *method* is set to **-materi\_displacement** the last calculated **-materi\_displacement** directions will be used. If *method* is set to **-materi\_velocity\_integrated** the last calculated **-materi\_velocity\_integrated** directions will be used. If somewhere the direction is not specified by the above, because the used direction is a null vector, then Tochnog will ask you to specify **safety\_slip\_grd\_method\_direction** additionally, and then that direction will be used there.

Default, if **safety\_slip\_grd\_method** is not specified, *method* is set to **-safety\_slip\_grd\_direction**.

### 6.1033 **safety\_slip\_grd\_method\_direction** *index dir\_x dir\_y dir\_z*

See **safety\_slip\_grd\_method**.

#### 6.1034 **safety\_slip\_grd\_segment\_n** *index n*

With this record you can specify how many segments in each part of the surface of the `grd` file will be used in the integration of the safety factor. In total the surface has  $nx*ny$  parts; each of these parts will be integrated with  $n*n$  segments. Default, if **safety\_slip\_grd\_segment\_n** is not specified, then  $n$  will be set to 10.

#### 6.1035 **safety\_slip\_multi\_linear** *index x\_first,0 y\_first,0 x\_first,1 y\_first,1 ... x\_last,0 y\_last,0 x\_last,1 y\_last,1 ...*

This record specifies multi linear lines along which the safety factor should be calculated.

All data with *first* specifies the first multi linear line. The  $x\_first,0$   $y\_first,0$  specifies the first point of the first line piece of the first multi linear line, the  $x\_first,1$   $y\_first,1$  specifies the second point of the first line piece of the first multi linear line which is also the first point of the second line piece of the first multi linear line, etc.

All data with *last* specifies the last multi linear line. The  $x\_last,0$   $y\_last,0$  specifies the first point of the first line piece of the last multi linear line, the  $x\_first,1$   $y\_first,1$  specifies the second point of the first line piece of the last multi linear line which is also the first point of the second line piece of the last multi linear line, etc. This last multi linear line should have an equal number of points as the first multi linear line.

With **safety\_slip\_multi\_linear\_n** you specify the number of multi linear lines that should be evaluated in the safety calculation; all multi linear lines to be evaluated will be put equidistant between the first multi linear line and the second multi linear line.

As a special option you can only specify data for the first multi linear line, and specify not data for the last multi linear line and not **safety\_slip\_multi\_linear\_n**; then only one multi linear line will be used.

See also **control\_safety\_slip**.

#### 6.1036 **safety\_slip\_multi\_linear\_n** *index n*

See **safety\_slip\_multi\_linear**.

#### 6.1037 **safety\_slip\_multi\_linear\_result** *index x\_0 y\_0 x\_1 y\_1 ... safety\_factor*

This record will after the calculation be filled with the multi linear line for the critical surface (for the multi linear lines circles with the same index).

#### 6.1038 **safety\_slip\_multi\_linear\_segment\_n** *index n*

With this record you can specify how many segments in a line piece of a multi linear line will be used in the integration of the safety factor. A high number of segments gives more accuracy but is time consuming. A low number of segments is less accurate but fast. Default, if **safety\_slip\_multi\_linear\_segment\_n** is not specified, then 10 segments will be used.

#### 6.1039 **safety\_slip\_set** *index index\_0 index\_1 index\_1 ...*

This records defines the indices of safety geometries belong to a set. For all safety geometries of a set, the minimal safety factor will be determined.

As a special option you can also define a range.

#### 6.1040 **safety\_slip\_set\_result** *index index safety\_factor*

This record will be filled after the calculation with the minimal safety factor of the geometries in the set.

#### 6.1041 **slide\_axisymmetric** *index switch*

If *switch* is set to **-yes** the slide defined by the **slide\_geometry** is axisymmetric.

#### 6.1042 **slide\_geometry** *index geometry\_entity geometry\_entity\_index*

This record generates slide friction forces when a material slides over the geometry specified by *geometry\_entity geometry\_entity\_index*.

This option comes handy when it is a priori known at which nodes sliding will occur, which is typically the case in an Eulerian calculation.

Also **slide\_plasti\_friction** should be specified.

See also **node\_slide**.

#### 6.1043 **slide\_plasti\_friction** *index phi c*

This record specifies friction for the **slide\_geometry** option. The maximum friction force between the material and the side surface equals  $c + F_n * \tan(phi)$  where  $c$  is the cohesion,  $phi$  is the friction angle in radians and  $F_n$  is the normal force.

The plastic yield function will become available in the records **node\_\_slide\_\_f**.

#### **6.1044** **slide\_\_plasti\_\_tension** *index sig\_\_t*

This record specifies maximum tensile force for the **slide\_\_geometry** option.

The plastic yield function will become available in the records **node\_\_slide\_\_f**.

#### **6.1045** **slide\_\_user** *index switch*

If *switch* is set to **-yes** the user supplied routine for slide friction is called.

See also the file **user.cpp** in the distribution.

#### **6.1046** **slide\_\_damping** *index damping\_\_n damping\_\_t*

This specifies the normal damping and tangential damping for sliding. See also **control\_\_slide\_\_damping\_\_apply**.

#### **6.1047** **slide\_\_stiffness** *index stiffness\_\_n stiffness\_\_t*

This specifies the normal stiffness and tangential stiffness for sliding.

The slide directions will become available in the records **node\_\_slide\_\_direction**. The slide forces will become available in the records **node\_\_slide\_\_force**.

See also **control\_\_slide\_\_stiffness\_\_apply**.

#### **6.1048** **solver** *solver\_\_type*

You can set here the solver type to one of solvers as specified in **control\_\_solver**. The solver set here holds for the entire calculation (as opposed to the **control\_\_solver** which only holds for the corresponding time steps). In fact, each **control\_\_solver** will be overwritten by a specified **solver**.

When using the bicg solver, consider also setting **solver\_\_matrix\_\_symmetric** to **-yes**, in order to speed up the speed of the bicg solver.

#### 6.1049 `solver__bicg__error` *error*

With *error* you set the termination error ratio between the initial and final error in the bicg iterations.

See also `control__solver__bicg__error`.

#### 6.1050 `solver__bicg__restart` *nrestart*

With *nrestart* you set the number of restarts in the bicg iterations.

See also `control__solver__bicg__restart`.

#### 6.1051 `solver__bicg__stop` *switch*

If *switch* is set to **-yes**, the calculation is stopped if the bicg solver does not converge. If *switch* is set to **-no**, the calculation is not stopped if the bicg solver does not converge.

See also `control__solver__bicg__stop`.

#### 6.1052 `solver__matrix__save` *switch*

If *switch* is set to **-yes**, the solver saves and applies the decomposed matrix, but not in case Tochnog thinks for some reason that the matrix needs to be decomposed at each timestep. This can save CPU time, since further decompositions of the matrix are not required anymore (only backsubstitution to find the solution vector).

If *switch* is set to **-no**, the solver does not save the decomposed matrix.

If *switch* is set to **-always**, the solver saves and applies the decomposed matrix, even in case Tochnog thinks for some reason that the matrix needs to be decomposed at each timestep.

This option is only available in combination with the pardiso solver. See also `control__solver__matrix__save`.

#### 6.1053 `solver__matrix__symmetric` *switch*

If *switch* is set to **-yes** then, if needed, matrices are symmetrized so that less memory will be needed and a symmetrical equation solver can be used.

#### 6.1054 **solver\_pardiso\_ordering** *ordering*

See also **control\_solver\_pardiso\_ordering**.

#### 6.1055 **solver\_pardiso\_out\_of\_core** *switch*

If *switch* is set to **-yes** the pardiso solver is called with a 'out of core' option. See for further the pardiso solver in the the intel mkl library.

#### 6.1056 **solver\_pardiso\_processors** *nproc*

Set the number of processors to be used by the pardiso solver. Only 1 or the maximum number of the computer is allowed, nothing in between. The pardiso solver in the intel mkl library can have problems with parallelisation; so if you use this option check your results.

Default *nproc* is set to 1 (no parallelisation).

#### 6.1057 **solver\_pardiso\_processors\_maximum** *switch*

If *switch* is set to **-yes** the maximum number of processors will be used for the pardiso solver. Else only 1 processor will be used for the pardiso solver. See also **solver\_pardiso\_processors**.

#### 6.1058 **strain\_settlement\_parameters** *index time\_global, start time\_plus reference\_creep\_strain\_rate reference\_time power\_n lateral\_factor*

With this option data items you can specify an extra vertical settlement creep strain. Think of geotechnics soil dumping as a typical example where after dumping some extra vertical straining shows up over time.

The vertical settlement creep strain of a soil particle is assumed to be:

$$\epsilon_{zz} = \frac{\dot{\epsilon}_r}{1 + \left(\frac{t - t_{plus}}{t_r}\right)^n}$$

The user supplied parameters are:  $\dot{\epsilon}_r$  as reference creep rate,  $t_{plus}$ ,  $t_r$  as reference time and  $n$  as power constant. Creep strain starts when the global time  $t_{global}$  reaches *time\_global, start*. So *time\_age, start* can be used to set where in the creep strain curve the material will start with creeping. The time  $t$  in this equation is the time elapse after the material has become active (so the time after dumping the material, which typically is different for each finite element).

The horizontal creep strains  $\epsilon_{xx} = f\epsilon_{zz}$  and  $\epsilon_{yy} = f\epsilon_{zz}$  are assumed to be a lateral factor  $f$  times the vertical creep strain.

This **strain\_settlement\_parameters** should be combined with the **mesh\_gravity\_activate\_time** option as follows:

```
...
mesh_activate_gravity_time 10 ...
mesh_activate_gravity_time_strain_settlement 10 -yes
strain_settlement_parameters 20 ...
...
```

The **mesh\_activate\_gravity\_time\_strain\_settlement** indicates that the mesh activation should not be used by itself, but is only used to determine element activation times needed for the **strain\_settlement\_parameters** option.

See also **strain\_settlement\_element\_group**.

**6.1059 strain\_settlement\_diagram** *index dof\_0 value\_0 dof\_1 value\_1*  
...

With the records **strain\_settlement\_diagram**, **strain\_settlement\_diagram\_dof** and **strain\_settlement\_diagram\_number** you can specify parameters of **strain\_settlement\_parameters** to be dependent on dof values (strains, stresses, ...) or calculated dof values (total pressures, ....).

In **strain\_settlement\_diagram\_dof** you can set a name of **dof\_label** (eg -sigyy) or of **post\_calcul\_label** (eg -to\_pres).

In **strain\_settlement\_diagram\_number** you can set the number of the parameter of **strain\_settlement\_parameters** to be made dependent (eg 1 for *time\_plus*, 2 for *reference\_creep\_strain\_rate* etc.). You are not allowed to specify number 0 (so for *time\_global,start*).

In **strain\_settlement\_diagram** you can set the dependency as sets dof-value. If the dof value is outside the diagram the parameter of the strain settlement will not change.

**6.1060 strain\_settlement\_diagram\_dof** *dof*

See **strain\_settlement\_diagram**.

**6.1061 strain\_settlement\_diagram\_number** *number*

See **strain\_settlement\_diagram**.

**6.1062 strain\_settlement\_element\_group** *index element\_group\_0 element\_group\_1 ...*

This record specifies the element groups for which the **strain\_settlement\_parameters** with the same parameters will be used. As a special option you can use **-all**, such that all elements groups will be used.

**6.1063 strain\_volume\_absolute\_time** *index time\_0 volume\_increase\_absolute\_0 time\_1 volume\_increase\_absolute\_1 ...*

See **strain\_volume\_element**.

**6.1064 strain\_volume\_element** *index element\_0 element\_1 ...*

With the **strain\_volume\_\*** data items you can specify an extra volumetric strain component which Tochnog should add to specified elements, element groups or a geometry. Think of geotechnics grouting as a typical example.

If you specify **strain\_volume\_\*** then  $\frac{1}{3}$  of the specified volumetric strain is imposed as xx-strain, yy-strain and zz-strain. The actual straining of elements in the calculation will depend on boundary conditions, external forces, etc. For example, if you have a calculation where all displacements are suppressed by boundary conditions, the actual deformation of elements is null, and the specified **strain\_volume\_\*** only leads to stresses. For example, if you have a 3d calculation where elements are free to deform the actual deformation of elements will become equal to the specified **strain\_volume\_\***. For example, if you have a 2d plain strain calculation where elements are free to deform the actual deformation of elements will be smaller than specified **strain\_volume\_\*** (since there is no deformation possible in the third direction).

Use **strain\_volume\_element** to specify element numbers for which the volume strain should be applied. Use **strain\_volume\_element\_group** to specify element group numbers for which the volume strain should be applied. Use **strain\_volume\_geometry** to specify a geometry for which the volume strain should be applied.

You can either specify relative volume strains (relative to the initial volume) or absolute volume changes. Use **strain\_volume\_relative\_time** to specify a time versus relative volume strain diagram. These relative volume strains should be specified as percentage (thus, 100 would be a volume strain equal to the initial volume, so 100 percent extra volume). Use **strain\_volume\_absolute\_time** to specify a time versus absolute volume increase diagram. These absolute volume increases should be specified as real volume (thus  $m^3$  if you use would meter  $m$  as length unit in your input file). Exactly one of **strain\_volume\_relative\_time** or **strain\_volume\_absolute\_time** should be given in the input file, not both. At times outside **strain\_volume\_relative\_time**, or **strain\_volume\_absolute\_time**, the relative volume strain, or absolute volume increase, are assumed to be zero.

If none of **strain\_volume\_element**, **strain\_volume\_element\_group** or **strain\_volume\_geometry** is given then the **strain\_volume\_relative\_time** or **strain\_volume\_absolute\_time** will be applied to all isoparametric elements.

The volumetric strain option presently is available only for small deformation analysis. The volumetric strain can be applied to isoparametric elements only. The volumetric strain is not available for membrane elements.

See also **post\_strain\_volume\_absolute** and **post\_strain\_volume\_relative**.

**6.1065 strain\_volume\_element\_group** *index element\_group\_0 element\_group\_1 ...*

See **strain\_volume\_element**.

**6.1066 strain\_volume\_geometry** *index geometry\_item\_name geometry\_item\_index*

See **strain\_volume\_element**.

**6.1067 strain\_volume\_relative\_time** *index time\_0 relative\_volume\_strain\_0 time\_1 relative\_volume\_strain\_1 ...*

See **strain\_volume\_element**.

**6.1068 support\_edge\_normal** *index stiffness\_normal stiffness\_tangential*

Distributed support of an edge (winkler foundation). The *stiffness\_normal* specifies the normal stiffness of the support per unit length in 2D, and per unit area in 3D. The *stiffness\_tangential* specifies the tangential stiffness. This option is meant for 2D and 3D calculations.

Also the record **support\_edge\_normal\_geometry** should be specified.

Attention: this option is only available for linear and quadratic isoparametric elements.

See also **node\_support\_edge\_normal\_force**.

### 6.1069 **support\_edge\_normal\_damping** *index damping\_normal damping\_tangential*

Distributed damping at an edge. The *damping\_normal* specifies the normal damping of the support per unit length in 2D, and per unit area in 3D. The *damping\_tangential* specifies the tangential damping. This option is meant for 2D and 3D calculations.

If you want to use **support\_edge\_normal\_damping** to absorb stress wave at the boundaries of the mesh (think of vibration or earthquake analysis), there are typical values to be used for the normal and tangential damping.

For absorbing boundaries the *damping\_normal* typically should be set to  $C_n \rho V_n$ . The parameter  $C_n$  typically is chosen as 1. The  $\rho$  is the material density. The pressure wave velocity is  $V_n = \sqrt{\frac{E_{oed}}{\rho}}$  with oedometric stiffness  $E_{oed} = \frac{(1-\nu)E}{(1+\nu)(1-2\nu)}$  where  $E$  is the Young's modulus, and  $\nu$  is Poisson's ratio. For absorbing boundaries the *damping\_tangential* typically should be set to  $C_t \rho V_t$ . The parameter  $C_t$  typically is chosen as 0.25. The shear wave velocity is  $V_t = \sqrt{\frac{G}{\rho}}$  with shear modulus  $G = \frac{E}{2(1+\nu)}$ .

Also the records **support\_edge\_normal** and **support\_edge\_normal\_geometry** should be specified.

Attention: this option is only available for linear and quadratic isoparametric elements.

See also **control\_support\_edge\_normal\_stiffness\_freeze** and **node\_support\_edge\_normal\_force**. See also **support\_edge\_normal\_damping** for automatic specification of damping properties.

### 6.1070 **support\_edge\_normal\_damping\_automatic** *index switch*

If you set *switch* to **-yes** this record generates damping just like the **support\_edge\_normal\_damping** record. Now however you do not need to specify the damping properties yourself; they are calculated by Tochnog using the Young value  $E$  and the Poisson ratio  $\nu$  from the isoparametric element attached to the support.

### 6.1071 **support\_edge\_normal\_damping\_automatic\_apparent** *index switch*

If you set *switch* to **-yes** this record generates damping just like the **support\_edge\_normal\_damping** record. Now however you do not need to specify the damping properties yourself; they are calculated by Tochnog using the apparent young and poisson value from the isoparametric element attached to the support.

**6.1072** `support_edge_normal_density` *index density\_normal density\_tangential*

Distributed density at an edge. The *density\_normal* specifies the normal density of the support per unit length in 2D, and per unit area in 3D. The *density\_tangential* specifies the tangential density. This option is meant for 2D and 3D calculations.

Attention: this option is only available for linear and quadratic isoparametric elements.

**6.1073** `support_edge_normal_element_node` *index element\_0 element\_1 ...*

Selects the element and local nodes for which the `support_edge_normal` record with the same *index* should be applied.

**6.1074** `support_edge_normal_element_group` *index element\_group*

Restricts the element group to which the `support_edge_normal` record with the same *index* should be applied.

**6.1075** `support_edge_normal_element_side` *index element\_0 element\_1 ... side*

Selects the elements and local side number for which the `support_edge_normal` record with the same *index* should be applied.

**6.1076** `support_edge_normal_factor` *index a\_0 a\_1 ... a\_n*

The same as `force_edge_normal_factor`, now however for the support stiffnesses (and not the force).

**6.1077** `support_edge_normal_force_initial` *index a\_0 a\_1*

This record allows you to specify an initial normal force in the support, linear varying in depth direction. The initial normal force actually is  $a_0 + a_1 * y$  in 2D, or  $a_0 + a_1 * z$  in 3D.

**6.1078 support\_edge\_normal\_geometry** *index geometry\_entity\_name geometry\_entity\_index*

Selects the area for which the **support\_edge\_normal** record with the same *index* should be applied. For example, **-geometry\_line 1** can be used in 2D, indicating that the nodes on line 1 get the distributed support.

**6.1079 support\_edge\_normal\_node** *index node\_0 node\_1 node\_2...*

Selects the nodes for which the **support\_edge\_normal** record with the same *index* should be applied. The *node\_0* etc. specify global node numbers.

**6.1080 support\_edge\_normal\_plasti\_compression** *index normal\_force\_minimum tangential\_force\_factor*

With *normal\_force\_minimum* you can limit the amount of compression force that a support can take. Any compression force lower than this *normal\_force\_minimum* will actually be set to *normal\_force\_minimum*. Typically you want to specify a negative value for *index normal\_force\_minimum*.

With *tangential\_force\_factor* you can model frictional slip in the tangential direction. The tangential force is limited to *tangential\_force\_factor* times the normal force. Larger tangential forces are not allowed.

This **support\_edge\_normal\_plasti\_compression** will only be used if the normal force does not exceed the maximum tension force as specified in **support\_edge\_normal\_plasti\_tension** or **support\_edge\_normal\_plasti\_tension\_double**.

All forces are per unit length in 2D, and per unit area in 3D.

**6.1081 support\_edge\_normal\_plasti\_friction** *index cohesion friction\_coefficient*

With this record you can limit the amount of friction force that a support can take. The maximum allowed friction force is the *cohesion* plus the *friction\_coefficient* multiplied with the absolute value of the normal force.

All forces are per unit length in 2D, and per unit area in 3D.

**6.1082 support\_edge\_normal\_plasti\_tension** *index switch*

If *switch* is set to **-yes** and the normal force in the support is tension, then all forces are set to 0. This models gap building between the support and the element edge.

#### 6.1083 **support\_edge\_normal\_plasti\_tension\_double** *index normal\_force\_maximum*

With *normal\_force\_maximum* you can limit the amount of tension force that a support can take. As opposed to **support\_edge\_normal\_plasti\_tension**, you can specify a non-zero value with this option. If a normal force higher than this *normal\_force\_maximum* occurs it will be set to *normal\_force\_maximum*, and tangential shear forces will be set to zero. Typically you want to specify zero or a positive value for *index normal\_force\_maximum*, although a negative value is also allowed.

Not both of **support\_edge\_normal\_plasti\_tension** and **support\_edge\_normal\_plasti\_tension\_double** can be specified.

All forces are per unit length in 2D, and per unit area in 3D.

#### 6.1084 **support\_edge\_normal\_plasti\_residual\_stiffness** *index factor*

In case of plasticity in a support you can require that Tochnog includes a part of the original elastic stiffness in the element stiffness matrix to get more stable iterations. The part of the original stiffness included needs to be specified with *factor*, between 0 and 1. The stiffness is only included in the matrix, and not in the right-hand-side; so it will only influence convergence behaviour, but not the final results if a sufficient amount of steps is taken. Default, if **support\_edge\_normal\_plasti\_residual\_stiffness** is not specified, *factor* is set to 0.

#### 6.1085 **support\_edge\_normal\_time** *index time load time load ...*

This record specifies a diagram with a multiplication factor for the support edge force. Linear interpolation is used to extend the *time load* values to the intervals between these pairs. Outside the specified time range a factor 0 is used.

If this record is not specified, a factor of 1 is applied at all times.

#### 6.1086 **target\_item** *index data\_item\_name data\_item\_index number*

See also: **target\_value**.

#### 6.1087 **target\_value** *index value tolerance*

This allows for testing the results of the calculation. Typically, *data\_item\_name* is **-node\_dof** but also other data items can be tested. The record with index *data\_item\_index* will be tested. If *data\_item\_name* is **-node\_dof** then *number* can be **-velx**, **-temp**, etc.

(see **dof\_label**); else, for example, *number* is 3 states that the fourth value needs to be checked. The result should not differ more from *value* than *tolerance*.

For a calculation with no problems, the tochnog.log file contains a line stating that the calculation did start followed by a line stating that the calculation did end. If this is not precisely the case, some problem did occur or the targeted results differ too much. In the example below it is checked that the pressure in node 6 does not differ more than  $1.10^{-5}$ .

```
target_item 0 -node_dof 6 -pres  
target_value 0 1.2 1.e-5
```

The checked value, 1.2 in this case, has been found from a previous computation that is regarded as reliable. The present computed value is compared with the earlier one. If they agree within the specified tolerance, 1.e-5 in this case, then Tochnog is silent. If they do not, then Tochnog writes an error message into the file "tochnog.log".

#### **6.1088**    **time\_calculation** *elapsed\_time\_in\_seconds*

Elapsed computer time up to moment of printing (wall clock time).

#### **6.1089**    **time\_current** *current\_time*

Current time in calculation.

#### **6.1090**    **timestep\_predict\_velocity** *switch*

Normally tochnog will use as prediction for velocities in a timestep the previous calculated velocities from the previous timestep.

However, if there is no inertia, and **convection\_apply** is **-no** tochnog will use as prediction for velocities in a timestep a zero velocity.

You can require that tochnog does the normal prediction from the previous timestep however by setting *switch* to **-yes**; you typically want to do that in eulerian calculations.

#### **6.1091**    **timestep\_iterations\_automatic\_apply** *switch*

If *switch* is set to **-no** any **control\_timestep\_iterations\_automatic** records will be neglected.

### 6.1092 **tochnog\_version** *index day month year*

This record contains the build day, the build month and the build year.

### 6.1093 **truss\_rope\_apply** *switch*

If *switch* is set to **-no**, any truss rope data in the input file will be ignored. This is done for all timesteps.

This option is convenient for testing your input file just linear, without the need to outcomment each and every part with truss rope data. See also **control\_truss\_rope\_apply**.

### 6.1094 **volume\_factor** $a_0 a_1 \dots a_n$

This data item defines a polynomial in space in 1D or 2D. The polynomial specifies the cross-sectional area (in 1D) or the thickness (2D) as function of the global  $x$  coordinate (1D) or the global  $x,y$  coordinates (2D). For example, in a 1D solid calculation it can be used to specify varying cross-sectional areas of bars, or in a 1D flow calculation it can be used to specify the cross-sectional area of a channel.

In 1D the polynomial is  $a_0 + a_1x$  (specify 2 values). In 2D the polynomial is  $a_0 + a_1x + a_2y$  (specify 3 values).

If this record is not specified, the cross-sectional area is 1 (1D) or the thickness is 1 (2D).

See also **volume\_element\_factor**.

### 6.1095 **volume\_factor\_x** $x_0 fac_{01} x_1 fac_{12} \dots x_n$

This specifies an in x-direction changing volume factor for elements. Left from  $x_0$  the factor is 1. From  $x_0$  to  $x_1$  the factor is  $fac_{01}$ . Etcetera. And right from  $x_n$  the factor is 1 again.

### 6.1096 **zip** *switch*

If *switch* is set to **-yes** all **\*flavia\***, **\*msh**, **vtk**, **\*.plt** and **\*dbs** files are zipped with the **gzip** program. The **gzip** program should be installed on your computer.

This comes convenient in large calculation with lots of output, where you want to use results later and save disk space during the calculation.

If also **control\_zip** is specified for a certain control index that overrules this **zip** for that control index.

6.1097 end\_data (last record of data part)

## 7 Runtime file

You can use a runtime file to give to Tochnog data on the fly (while it is running). The runtime file will be read at the start of each time step. The runtime file needs to have the same name as the input file, with the extension **run** instead of **dat** however. Suppose the name of the normal input file is **beam.dat**, then the name of the runtime file is **beam.run**. The runtime file always needs to be ended with two **end\_data** statements.

As a typical example you can use this runtime file when you are doing a long calculation and you decide while the calculation is running that you want extra output. Suppose the normal input file **tochnog.dat** contains:

```
...  
control__timestep 100 ...  
...
```

Then you can decide to get some extra GID plotting files, while Tochnog is already running, by using the runtime file **tochnog.run** with:

```
control__print__gid 100 -yes  
end__data end__data
```

When you want to de-activate the printing of GID files again then set the runtime file to:

```
control__print__gid 100 -no  
end__data end__data
```

As a special option, you can use **exit\_\_tochnog -yes** in the runtime file; then Tochnog will exit the calculation after printing the complete database and GID files.

After the runtime file is read, it will be automatically deleted by Tochnog.

## 8 Interaction analyzes and advanced analyzes

### 8.1 Fluid-structure interaction

If a solid construction interacts with a fluid, both the solid and fluid can be modeled with the materi equation. Interaction forces between solid and fluid will automatically be generated. If required, a temperature field may be imposed. An example of a input file is given below

```
...
materi_velocity
materi_stress
condif_temperature
end_initia
...
element_group -ra -from 0 -to 100 -ra 1
element_group -ra -from 101 -to 200 -ra 2
...
type 1 -materi -condif
group_materi_elasti_young 1 ...
group_materi_memory -updated
group_condif_conductivity 3 ...
...
type 2 -materi
group_materi_elasti_compressibility 2 ...
group_materi_viscosity 2 ...
group_materi_memory -updated_linear
group_condif_conductivity 2 ...
...
```

Elements 0-100 are solids (with temperature) and elements 101-200 are fluids (with temperature).

### 8.2 Consolidation analysis: ground water flow in deforming solid

The ground water flow equation can be combined with the materi equations. The solid will deform due to the ground water flow pressure gradient and ground water flow pressure will change due to solid volume changes. An example of a input file is given below

```
...
materi_velocity
materi_stress
```

```

groundflow__pressure
end__initia
...
groundflow__consolidation__apply -yes ...
groundflow__density ...
groundflow__phreatic__level ...
...
group__type 0 -materi -groundflow
group__materi__elasti__young 0 ...
group__materi__memory -updated
group__groundflow__capacity 0 ...
...

```

The stresses as initialized by **materi\_\_stress** are effective stresses. Internally the program calculates with total stresses (effective stress + total pressure) in the material equilibrium equation. You can obtain the total stresses for postprocessing by means of the **post\_\_calcul** option.

To account for the gravitational stresses, use a density  $\rho_{sat}$  in the **group\_\_materi\_\_density** record. Here  $\rho_{sat}$  is the saturated density of the groundwater-soil mixture (mass of soil + water per unit volume of the soil-water mixture). Also specify the gravitation in the **force\_\_gravity** record and, if required, also the **force\_\_gravity\_\_time** record to apply the gravitation slowly.

### 8.3 Heat transport in ground water flow

Heat transport in a ground water flow can be analyzed by combining the convection and diffusion of heat equation with the ground water flow equation. Now the velocity in the convection and diffusion of heat equation is taken from the groundflow velocity field (  $\beta_i = v_i^g$  ) if **groundflow\_\_velocity** is initialized. An example of a input file is given below

```

...
groundflow__pressure
groundflow__velocity
condif__temperature
end__initia
...
type 0 -groundflow -condif
group__groundflow__compressibility 0 ...
group__condif__conductivity 0 ...
...

```

If both **materi\_\_velocity** and **groundflow\_\_velocity** are initialized,  $\beta_i = v_i + v_i^g$ .

## 8.4 Heat transport in materials

Heat transport in a material can be analyzed by combining the convection and diffusion of heat equation with the materi equations. In this way thermal stresses or heat induced convection can be analyzed. Now the velocity in the convection and diffusion of heat equation is taken from the velocity field (  $\beta_i = v_i$  ). An example of a input file is given below

```
...
materi_velocity
materi_stress
condif_temperature
end_initia
...
type 0 -materi -condif
group_materi_elasti_young 0 ...
group_materi_expansion 0 ...
group_materi_memory 0 -updated
group_condif_conductivity 0 ...
...
```

## 8.5 Restart a calculation

You can use a dbs file to restart a calculation. In fact, a dbs file is an input file itself. It contains the record **icontrol** which contains the last control index actually performed with the previous calculation. You can add more **control\_\*** records and start the file again; it will then continue with these new **control\_\*** records.

You cannot use dbs files with contain **control\_repeat** for restarting a calculation.

## 9 Final topics (input trouble, save memory /CPU time, ...)

### 9.1 Environment symbols

Records with a length of 1, and no index, you can also set via an environment symbol. You need to use capital characters in doing so. Typical examples are

- **PROCESSORS 4**
- **PRINT \_GID \_CALCULATION -no**
- **PRINT \_GMSH \_CALCULATION -yes**
- **PRINT \_NODE \_GEOMETRY \_PRESENT -yes**

In windows set environment symbols in your advanced system settings. In a linux bash shell set environment symbols in your `.bashrc` file (eg **export PROCESSORS=4**).

### 9.2 Checking your geometry \_\* records

Set **print \_node \_geometry \_present -yes** and set **print \_element \_geometry \_present -yes**. Then look with **gmsh** if the geometries are like you want.

### 9.3 Continuing an analysis

- Copy the database from the previous calculation to a new file, e.g. **new.dat**.
- Run a new calculation with **new.dat**.

This can also be done with a database that is written as intermediate database in a previous calculation, for example directly after gravity. See also **icontrol**.

### 9.4 Use -node as geometry entity.

As a special option you can use a node as a geometrical entity. For example the following imposes a boundary condition on the temperature of node 6:

```
bounda _dof 10 -node 6 -temp
```

Notice that **-node 6** is used in the format of a geometry entity.

## 9.5 Use -geometry\_list as geometry entity.

As a special option you can use a list as a geometrical entity. For example the following imposes a boundary condition on the nodes of geometry list 6:

```
geometry_list 6 54 43 26 38 62  
bounda_dof 10 -geometry_list 6 -temp
```

## 9.6 List input files with options

You can search for input files in your distribution which contain multiple words. For example change to the test/other directory. Suppose you want to see in which files you can see transient consolidation in a deforming soil.

In linux use the following command to list input file:

```
grep -il materi_velocity *.dat | xargs grep -il groundflow_capacity | xargs grep  
-il groundflow_consolidation.
```

In MS Windows use:

**windows explorer - Search - Advanced options - File contents**

and search for

**materi\_velocity AND groundflow\_capacity AND groundflow\_consolidation.**

## 9.7 Geometrically linear material

Either do this:

- Initialise **-materi\_velocity** and **-materi\_displacement**
- Use **-total\_linear** for the material.

or do this:

- Initialise **-materi\_velocity** and **-materi\_velocity\_integrated**
- Use **-fixed\_in\_space** for **mesh**
- Use **-updated\_linear** for the material.

## 9.8 Dynamic calculations

Dynamic calculations are triggered by setting **inertia\_apply -yes**. Take care that you have specified all required data, like material density, etc.

In case you want to reduce numerical damping, you can use the following piece of input file, notice the **materi\_dynamic**.

```
...
materi_displacement
materi_velocity
end_initia
...
inertia_apply -yes
materi_dynamic -yes
...
control_timestep .....
...
```

For heavy non-linear calculations this may converge worse than the default euler backward time integration.

To get damping similar to rayleigh damping in structural dynamics use:

```
...
group_materi_damping ... (similar to rayleigh damping mass term, use
rayleigh alpha * material density )
group_materi_viscosity ... (similar to rayleigh damping stiffness term, use
rayleigh beta * material young )
...
```

See also **materi\_dynamic** to influence numerical damping in dynamic calculations with solid materials.

## 9.9 Input file syntax

- If you don't understand the syntax of an option, please look in the tochnog/test/other directory for example files. Under linux search for the command, eg **grep control\_print\_filter \*.dat** to get example files with **control\_print\_filter**.

## 9.10 Check large calculations

- Set both **solver -none** and **linear\_calculation\_apply -yes** ; run and check in gid the boundary conditions, forces, change of element groups, etc. In a complex model you can check geometries that you use by imposing an artificial boundary on them, eg **bounda\_dof ... -temp** with value 1, and look in gid if you see that boundary condition showing up at the correct nodes.
- Only set **linear\_calculation\_apply -yes** ; run and check linear solution fields.
- Do not set anything special ; run and check solution fields.

## 9.11 Diverging calculations

- Try the linear elements **-bar2**, **-quad4**, **-tria3**, **-hex8** and **-tet4** in stead of quadratic elements.
- Try **solver\_matrix\_save -no** (always setup new system matrix)
- Try **group\_materi\_plasti\_mohr\_coul\_direct** i.s.o. **group\_materi\_plasti\_mohr\_coul**
- Try small fixed timesteps (do not use automatic time stepping).
- Try more iterations with **control\_timestep\_iterations**.
- Try a lower interface stiffness.
- Try higher water capacity in calculation with consolidation (so water less stiff, anyway not too stiff relative to soil)).
- Set **group\_interface\_materi\_residual\_stiffness** to 1.

## 9.12 Saving CPU time

- Check that the computer doesn't swap to disk (use top in linux, use task manager in windows). In case of swapping lower the memory usage (see the section 'Saving computer memory').
- For large calculations with many **post \*** commands: use **post\_apply -no** and use **control\_post\_apply index -yes** only at the moment that you actually need post results

## 9.13 Saving computer memory

Try the following steps, in order of priority:

- **solver\_matrix\_symmetric -yes**.

- **solver -matrix\_iterative\_bicg.**
- Use **bounda\_\_alternate.**
- If possible, don't use extreme large indices (since memory is allocated for all indices).

## 9.14 Inaccurate results

- Set the interface stiffness to about 10 times the neighbouring element young divided by the neighbour length.
- If a structure is submerged in water, eg a one-side submerged dam, you need to impose the correct pressure condition; but you also need to impose the water loading by a **force\_\_edge\_\_water.**

## 9.15 Element sides

This sections defines node numbers for element sides 0, 1, ... respectively.

For a **bar2** element the sides have the nodes numbers 0 and 1.

For a **tria3** element the sides have the nodes numbers 0,1 and 1,2 and 2,0.

For a **tria6** element the sides have the nodes numbers 0,1,2 and 0,3,5 and 2,4,5.

For quad elements the sides are in the order below, upper, left, right; see the pictures in **elements.**

For hex elements the sides are in the order below, upper, front, back, right, left; see the pictures in **elements.**

For a **tet4** element the sides have the nodes numbers 0,1,2 and 0,1,3 and 1,2,3 and 0,2,3.

For a **tet10** element the sides have the nodes numbers 0,1,2,3,4,5 and 0,1,2,6,7,9 and 2,4,5,7,8,9 and 0,3,5,6,8,9.

For a **prism6** element the sides have the nodes numbers 1,2,3 and 4,5,6 and 1,2,4,5 and 0,2,3,5 and 0,1,3,4.

For a **prism15** element the sides have the nodes numbers 0,9,1,11,10,2 and 3,12,4,14,13,5 and 0,9,1,6,7,3,12,4 and 1,10,2,7,8,4,13,5 and 0,11,2,6,8,3,14,5.

For a **prism18** element the sides have the nodes numbers 0,1,2,3,4,5 and 12,13,14,15,16,17 and 0,1,2,6,7,8,12,13,14 and 2,4,5,8,10,11,14,16,17 and 0,3,5,6,9,11,12,15,17.

## 9.16 Badly shaped elements

Each element should have at maximum one common side with a neighbouring element. For example two neighbouring quad4 elements have only one common side in a proper element mesh; if the neighbouring quad4 elements have two sides in common, the elements are badly shaped.

Some tochnog options will not work correctly if the mesh contains badly shaped elements.

## 9.17 Youtube

Tutorial movies can be found on <https://www.youtube.com/channel/UC7qvITX-SLwA4RuqMPYBmDQ>

## 9.18 External programs.

- <http://www.gidhome.com> Commercial pre- and postprocessor; easy. It can write for Tochnog input directly. It can read results both from **control\_print\_gid** and from **control\_print\_vtk**. See the **gid** directory in your distribution.
- <http://mecway.com> Commercial finite element program; easy. It can write for Tochnog **input\_abaqus**. It can read results from **control\_print\_gmsh**.
- <http://www.gnuplot.info/> Free x-y plotter; easy. It can read results from **control\_print\_history** and **control\_print\_data\_versus\_data**.
- <http://gmsh.info> Free pre- and postprocessor; complex. It can write for Tochnog **input\_abaqus**. It can read results from **control\_print\_gmsh**.
- <http://www.paraview.org> Free postprocessor; complex. It can read results from **control\_print\_vtk**.
- <http://www.freecadweb.org/> Free CAD program; complex. It can write for Tochnog **input\_abaqus** and read results from **control\_print\_frd**.
- [http://lace.fs.uni-mb.si/wordpress/borovinsek/?page\\_id=41](http://lace.fs.uni-mb.si/wordpress/borovinsek/?page_id=41) Free prepomax pre- and postprocessor for MS Windows; easy. It can write for Tochnog **input\_abaqus** and read results from **control\_print\_frd**. Isoparametric elements only.
- <http://www.bconverged.com/download.php> Free postprocessor CGX for MS Windows; easy. It can read results from **control\_print\_frd**.
- <https://www.mikepoweredbydhi.com/products/feflow> Dedicated ground water analysis program. Tochnog can read the mesh and hydraulic pressure heads with **input\_feflow\_\***.
- <https://ngsolve.org/> Free preprocessor in 3D. Tochnog can read the nodes and elements.

### 9.19 Forces are setup in the element loop in timesteps

The records `force_edge`, `force_edge_normal`, `force_edge_projected`, `force_volume`, `condif_heat_edge_normal`, `condif_convection_edge_normal` and `condif_radiation_edge_normal` are evaluated inside the element loop. Hence, the resulting nodal forces only get their values after a timestep is performed (since the element loop is performed in time steps).

### 9.20 Running in a Microsoft windows bash shell

When you want to run the linux executable in a Microsoft windows bash shell you need to set the environment symbol `KMP_AFFINITY` to disabled. So do **`export KMP_AFFINITY=disabled`** in the windows bash shell.

## 10 User supplied subroutines

Several skeleton user supplied subroutines are available in the file **user.cpp**. As a special option you can use an ABAQUS **umat.f** (ABAQUS is a trademark of Dassault Systemes; see [HTTP://www.abaqus.com](http://www.abaqus.com) for the ABAQUS homepage). See also **group\_materi\_umat** in this manual. We do not support any compilation, linking or run-time problems with user supplied routines.

We only have available **user.cpp** and **umat.f** on linux 64 bit.

We use ourselves the linux version specified in **linux\_version.txt** file in the user supplied distribution. If you want to use the user supplied routines it is convenient to also use the same operating system in order to prevent compiling and linking problems; for this distribution the needed libraries are supplied.

If you insist on using another distribution than we do, you should install yourself the needed libraries (with commands like: `sudo apt-get install gcc-7 g++-7`). For the distribution of **linux\_version.txt** the needed libraries are supplied.

Do the following:

- Download the **tochnog\_linux\_64\_bit\_user\_supplied.tar.gz** distribution.
- In the user supplied distribution read **README\_UMAT\_USER.txt**
- In the user supplied distribution look in the **makefile** how to compile.
